Archaeological excavation of Predynastic settlements shows that the cultures of Upper and Lower Egypt were distinct prior to the rise of unified Egypt. The northern Predynastic culture is usually referred to by scholars as the Maadi Cultural Complex (ca. 4000–3200 BCE). The southern cultures are more heavily subdivided by archaeologists. The earliest is Badarian (ca. 4400–4000 BCE) followed by Amratian/Naqada I (4000–3500 BCE), which is then followed by Gerzean/Naqada II (3500–3200 BCE). By around 3200 BCE, Naqada culture seems to have spread to the north, replacing the Maadi culture, and thus the period from about 3200–3000 BCE is referred to as Naqada III for all of Egypt. A problem for scholars attempting to understand the rise of the Egyptian state is to understand how and why the Naqada culture expanded northward.

Much of the evidence for the Naqada culture comes in the form of cemeteries (which have been more thoroughly explored by archaeologists than other types of settlements). One of the most useful cemetery sites for understanding the transformation of Naqada culture through phases I–III is the Umm el-Qaab cemetery at Abydos. In the Naqada I period, the burials at

► THE NARMER PALETTE

Found in the votive deposit of a temple to Horus in Hierakonpolis, this stone palette was designed for commemorative purposes as well as to house ceremonial eye paint, yet it is most well known for its historical significance. Inscribed on the palette is the earliest readable name of a king, Narmer, marking this king and his palette as the beginning of an epoch in Egyptian history. The two sides of the palette depict the king vanquishing enemies (with the help of a falcon god, presumably Horus), wearing the crown of Upper Egypt on one side and Lower Egypt on the other. Egyptologists long held that this was a representation of the unification of Egypt, but for some time now this point has been called into question. Furthermore, the palette plays a crucial role in Egyptian art history. While continuing motifs of Egyptian predynastic history, such as the smiting scene and the containment of chaotic creatures, it also marks the advent of artistic tools, such as registers, that would become standard convention throughout Egyptian history. Thus, both historically and artistically the Narmer Palette represents a crucial pivot in the study of ancient Egypt.

—Kerry Muhlestein

King Narmer smiting an enemy, from the Palette of Narmer, about 3000 BCE. (Bettmann/Corbis)

Abydos are relatively undifferentiated, meaning that there is not much difference in the construction of the graves or in the types of goods buried with the deceased. Scholars extrapolate from this evidence that this was a relatively egalitarian society. By Naqada II, however, there is significantly more variation in the graves. Especially prominent in the wealthier graves are foreign imports (many from Syria-Palestine) and goods that required highly specialized production. Thus, scholars believe that this reflects increasing divisions within the society whereby the power of the wealthiest members of the society may have been related to control of trade routes and/or the production of elite goods. In Naqada III, Abydos is home to the first kings of Egypt, the kings of the so-called Dynasty 0 (named as such since these kings all predate the

kings of Dynasty 1). Among these royal graves is Tomb U-j, which consisted of 12 rooms and contained over 400 jars from Syria-Palestine. Tomb U-j also contained about 150 small labels, which constitute the earliest attested examples of hieroglyphic writing. No doubt the invention of writing played a major role in facilitating the development of a large administrative structure in the early Egyptian state.

Based on the evidence from Abydos and elsewhere, scholars reconstruct that throughout the Naqada II period, Naqadan society became increasingly stratified and concerned with long-distance trade. This culture gradually spread northward until by Naqada III it had fully replaced the Maadi culture in the north. This replacement may have been through military conquest of the north, but there is no archaeo-

logical evidence for this, and a number of other mechanisms of cultural replacement could equally be postulated. Bruce Trigger has argued that three “statelets” existed (at Naqada, Hierakonpolis, and Abydos), and through competition, one of these statelets emerged as dominant. Barry Kemp argues that the Naqada II, a “proto-kingdom,” evolved out of an originally egalitarian community, and this proto-kingdom conquered the north in the Naqada III. Both of these reconstructions are possible and logical, but there is insufficient evidence to prove either of them.

The Development of the State in Mesopotamia

Sargon (Sharrum-kin, or “true king”), the founder of the Akkadian empire, epitomized the successful king, beloved of the gods, becoming the role model for later dynasts keen to demonstrate their continuity with the glories of the past. Though there had been other kings over the previous century who had sought to expand their leadership beyond the city-state level, Sargon, founder of the Akkadian dynasty, was the first Mesopotamian king to fully unify the city-states of Sumer and Akkad to create a regional territorial state. Thus, it is Sargon to whom historians look for the origins of the state in Mesopotamia.

Historians are fortunate in having substantial evidence for Sargon’s activities. Many inscribed monuments set up by Sargon and his successors were assiduously copied by later scribes, and a few inscribed objects still survive. These contemporary records provide genuine historical information through which a picture of the Akkadian dynasty can be reconstructed. A body of legend also accumulated around the Akkadian

➤ NARAM-SIN AND THE GODS

In contrast to his grandfather’s heroic status, the third Akkadian king, Naram-Sin, despite his achievements, was remembered in later literary accounts as the epitome of hubristic arrogance and impiety, responsible for the downfall of his dynasty, at least in conservative scribal circles.

In his own inscriptions, Naram-Sin claimed that his defeat of nine hostile kings in a series of battles won him the gratitude not only of the citizens of Agade but even of the gods, who invited him to become the patron deity of Agade. Naram-Sin’s elevation to divine status then allowed him to lay claim to the temple lands and revenues of the city and thence of the empire it controlled. Traditionalist outrage at this impiety was later rationalized in the story the Curse of Agade.

According to this tale, Ishtar (Inanna) gained permission from Enlil to take up residence in Agade as the city deity, bringing wealth, prosperity, and joy. Later, however, Enlil took offense at some action of Naram-Sin and withdrew his favor. Naram-Sin attempted unsuccessfully to change the god’s mind and in his anger and despair sacked Enlil’s temple, the Ekur, demolishing the buildings and carrying off the temple treasures to Agade. The gods fled the city; Enlil brought down the savage hordes of the Gutu upon it, and it was utterly destroyed.

There is no truth in this story. Naram-Sin made pious offerings at the Ekur, where he was held in honor long after his death. He refurbished the temple at great expense, a work completed by his successor, Shar-Kali-Sharri, who ruled for a quarter of a century before the Gutu (invaders from across the Zagros Mountains) made a significant impact on Akkadian affairs.

—Jane R. McIntosh

kings by the time of the next empire, that of the Third Dynasty of Ur (Ur III), and reflects later propaganda more than historical truth. Sargon’s origins are unknown; he was probably from the northern part of southern Mesopotamia and from a humble background. According to legend, he was the son of a priestess and a man from the eastern mountains. After his birth, the priestess cast him adrift on the river in a reed basket; he was rescued by Aqqi, a water carrier, who raised

him as a gardener. In his youth he served Ur-Zababa, king of Kish, whom he succeeded in circumstances whose details are now lost.

Sargon went on to win 34 battles, gaining control of the southern Mesopotamian cities by defeating their king, Lugalzagesi. Parading Lugalzagesi as a prisoner before the Ekur (Enlil's temple) in Nippur in effect demonstrated the transfer of authority from him to Sargon. Sargon also conquered Elam and towns to the north and west including Mari and Ebla. His inscriptions claim that he controlled areas as far afield as "Silver Mountain" (the Taurus range) in Anatolia and that his dominions stretched from the Upper Sea to the Lower Sea, in which he symbolically washed his weapons.

Like Lugalzagesi, who had made similar claims, Sargon's authority was probably closely linked to control of trade and of centers on trade routes rather than involving large-scale territorial conquest. Nevertheless, in southern Mesopotamia at least, Sargon established a unified state that exercised hegemony over all the traditionally independent city-states: a new political form for all that it was couched in the traditional language "King of the Land, King of Kish" and, like Lugalzagesi, "King of the four rims of the world."

Sargon established a new city as his capital. Agade, whose name may mean "ancestral town," was a minor settlement until Sargon brought it to prominence. A later poem, "The Curse of Agade," describes its architectural and cultural splendors, commercial success, and prosperity. Its glory did not survive the Akkadian period, and today its location is unknown. It was probably situated somewhere between Babylon, Kish, and Sippar.

The Origins of the Chinese State

At some point during the period from 4000 to 1000 BCE, the disparate Neolithic communities in China became somewhat unified, if not politically at least culturally. It becomes possible to speak of China as a political entity. Exactly when this happened and how it happened are some of the more interesting questions that Chinese archaeologists and historians are attempting to solve.

The traditional view of Chinese history describes three main periods in Chinese prehistory: the period of the gods, the period of the demigods, and the period of the sage kings. The last of the sage kings, Yu, inaugurates the first traditional historical period in China, the Xia dynasty. Yu, according to tradition, binds the 10,000 separate states into a unified whole. The Xia dynasty is then followed by the Shang dynasty that is then followed by the Western Zhou period.

Modern historians questioned the historicity of this traditional conception of history. The Xia dynasty was thought to be more mythical than historical. However, as archaeological excavations revealed more about ancient China, it became clear that the traditional genealogies from the Shang dynasty were relatively accurate, and the idea of a real Xia dynasty became less far-fetched. Archaeological work at Erlitou seems to have confirmed that, in fact, there may have been a historical Xia dynasty and that the traditional view of Chinese history was not as inaccurate as modern scholars had assumed.

Yet problems still remained with the traditional schema of early Chinese history. The sequential order of the three dynasties did not work well with the archaeological evidence, which seems to indicate that these dynasties all would have existed at overlapping times. Scholars have posited a more horizontal view of these three dynasties, suggesting that the Xia, Shang, and Western Zhou were just three of many indepen-

dent states that existed prior to the formation of the Chinese imperial state. Traditional historians had simply tried to fit these three dynasties into a sequential order that better fit the traditional view of historical change in China, that single dynasties rose and fell in a unified China throughout China's past. Modern scholars, who no longer feel compelled to recognize that China had always been unified, argue that China, on the eve of the imperial period, was actually ruled by a number of independent states that were gradually unified. Scholars who argue for this conception of Chinese prehistory call this the Three States period. There is significant archaeological evidence of warfare and conflict during this time period, indicating that these smaller states did not coexist peacefully and that the gradual unification of China was brought about through military force.

It needs be noted that there is no consensus that the archaeological discoveries at Erlitou should be considered Xia; many still believe that the Xia is an entirely mythical creation with no basis in history. Only further excavations and research will answer questions on the origin of the Chinese state.

COMMUNIST CHINA AND CONCEPTIONS OF THE SHANG

It was only after the 1950s, under communism, that multi-ethnic nationalism began to affect archaeology, which is evident in the shift of emphasis from the central plains (*Zhongyuan*) to a focus on multiregional development. It is not surprising, therefore, that the choice of locations for early excavations by Chinese archaeologists was based on the primary concern of the search for the indigenous cultural origins of the Han Chinese. Moreover, influenced by the May Fourth Movement of 1919, the traditional Confucian ways of learning were criticized while Western science and field methodology became influential. A group of young historians, referred to as "doubters of antiquity" (*yigupai*) and led by Gu Jiegang (1893–1979), developed a skeptical view of textual accounts of Chinese history. Their mission was to search for scientific evidence to reconstruct Chinese history. Archaeology, therefore, was endorsed by the *yigupai* as a scientific device to achieve this goal.

■ Introduction: Secondary States

In the previous section, we discussed the origins and features of early states in this period. These states are what anthropologists call "primary states." Primary states are states that arose through internal causes, not based on

interaction with other states. In other words, there were no other states nearby that provided a model for the development of that form of political organization. During this time, primary states included Egypt and the various states in

Mesopotamia and China. Scholars debate whether or not a state emerged in India at this time; if one posits that there was a state, then this would also be a primary state.

Secondary states are states that arose in the shadow of other state societies. These secondary states appear in close proximity with larger states that appeared earlier. It is usually assumed that at the very least these primary states provided a political model for the secondary state. In this era, most of the secondary states that have so far been identified seem to have coalesced in response to hostile interactions with nearby primary states. The Nubian Kingdom of Kush (located in what is now called the Sudan) formed in response to pressures from its northern neighbor Egypt. The Elamite states in Iran formed into states in response to the imperialistic advances of the Mesopotamian states to the west, in what is now known as Iraq. Mesopotamian incursions into Anatolia may also have played a part in the creation of smaller states in that region. The Hittite state, in what is now Turkey, was in frequent conflict with Egypt and Mesopotamia.

Complex Chiefdoms and States in Nubia

During the Nubian Bronze Age (approximately 3000–1000 BCE), complex chiefdoms arose in the region of Africa now known as the Sudan. Located along the Nile River, Nubia's history is intricately tied to Egypt's. Egyptian material culture (especially pottery) is found in great quantities at most Nubian sites. Nubia's close proximity to Egypt and its wealth of natural and human resources made it the subject of Egyptian imperial aspirations throughout much of the Bronze Age, and the development of chiefdoms in Nubia was certainly influenced by interactions with this larger state.

The region of Nubia closest to Egypt is called Lower Nubia. There is only minimal evidence for habitation in this region from the second Egyptian dynasty to the fifth Egyptian dynasty other than some small Egyptian settlements. It is likely that the Egyptians had driven people

from this region for security purposes. Starting around 1400 BCE, a local population emerges again in this region, referred to by archaeologists as Nubian C-Group, after the distinctive pottery associated with this culture. Archaeological excavations have shown that Nubian C-Group people were warriors; weapons caches have been recovered from a number of burials.

The best evidence for the political organization of the Nubian C-Group people comes from archaeological excavations and Egyptian historical accounts. With the exception of excavations at the city of Areika, most of the archaeological evidence for C-Group people comes from cemeteries. These cemeteries display marked differences in wealth and status through variation in amounts (and values) of associated grave goods and through variation in size and quality of the actual burial structures. Over 1,000 graves have been identified at Cemetery N at the site of Aniba. While most of the grave goods had been looted long ago, excavators were still able to identify elite graves because of their substantially larger size and separate location from smaller graves in the cemetery. This evidence for some elite differentiation is consistent with what scholars expect to find in a society organized into small chiefdoms, where a local elite rules from a small village over a relatively small region.

Egyptian historical accounts support the assertion that Lower Nubia in the Bronze Age was politically organized into small chiefdoms. Most important is the account of Harkhuf's travels through Africa. Harkhuf was a minor Egyptian official of the Sixth Dynasty who was responsible for organizing trade ventures into Africa on behalf of the Egyptian government. Accounts of his deeds are preserved (according to typical Egyptian custom) on the walls of his tomb, located at Elephantine. In Harkhuf's description of donkey caravans that traveled south through Africa, he discusses the regions of Wawat, Irjet, and Setju, which most scholars believe were located in Lower Nubia. This is a relatively small region ruled by three leaders, called *heka* in the Egyptian language. These heka, according to Harkhuf, were governed together by a single, more powerful ruler. This account is consistent with the archaeological evidence from the cem-

eteries. Around 2000 BCE, Egypt invaded Lower Nubia and incorporated the Nubian C-Group people directly into its empire.

Evidence for political governance in Upper Nubia in the south is less clear, but it is possible that a state-level society (and at the very least a powerful complex chiefdom) emerged in this region during the Bronze Age. Archaeologists refer to this as the Kerma culture (named after the large site of Kerma); the ancient Egyptians referred to it (in some periods) as the Kingdom of Kush.

Unlike Lower Nubia, Upper Nubia was not abandoned between the second and fifth Egyptian dynasties. Egyptian pottery is rare at early Kerma sites, indicating that contact between these polities was minimal. Egyptian pottery is much more common at Kerma sites after 2000 BCE, once Lower Nubia had been incorporated into the Egyptian empire. Prior to 2000 BCE, there is ample evidence for social stratification and elite differentiation, primarily in the elaborate graves that have been excavated. Most scholars believe that during this time the Kerma

➤ SCHOLARLY CONTROVERSY—DID THE IDEA OF “THE PHARAOH” ORIGINATE IN NUBIA?

Bruce Williams proposed an interesting idea based on excavations at the cemetery site of Qustul in Lower Egypt. He suggested that the traditional understanding of Egyptian-Nubian relationships was backward and that prior to the Bronze Age, Lower Nubia (the A-Group people) had controlled Upper Egypt and that Nubians had introduced the idea of pharaonic kingship to the Egyptians. Williams came to this conclusion based on the lavish graves in the small cemetery (called “L”) at Qustul. These graves had many elaborate Egyptian artifacts, which is not unusual for a Nubian cemetery. But what was unusual were typical Nubian artifacts (such as incense burners) decorated with iconography that is associated with royalty in later times in Egypt. If this was the case, then it appeared that the Egyptians had imported the idea of a king (and thus a centralized state government) from Nubia. However, subsequent excavations of the royal graves at Abydos (in mainland Egypt and the final resting place of some of the earliest Egyptian royalty) have uncovered royal tombs, and this same royal iconography dates earlier than the Qustul cemetery, so the theory of a Nubian birth-place for kingship has been largely abandoned.

—Kevin M. McGeough

people were organized into small-scale chiefdoms like those in Lower Nubia. Most scholars agree that after Egypt conquered Lower Nubia, the Kerma culture developed into a larger complex state, the state referred to as Kush in Egyptian sources. By 1600 BCE, Kush was a state that rivaled Egypt, usually engaging in friendly trade relations but threatening enough to require the Egyptians to set up defensive outposts and eventually incorporate the region into the Egyptian empire in the New Kingdom.

Early Iran

Although divided from Iraq by the Zagros Mountains, civilization in ancient Iran developed in tandem with the civilizations of Mesopotamia. In fact, most of our knowledge of ancient Iran comes from historical records left by the ancient Mesopotamians. Mesopotamian scribes referred to Iran as Elam, a name that the ancient Elamites did not use to describe themselves. Elam referred to the western area of the region now known as Iran, which, as in modern times, was a land that is quite culturally diverse. Now, scholars theoretically use the designation “Elam” to refer to the region when the Elamite language was in use, but in actual practice usage varies considerably.

Geographically, Elam can be divided into two zones: the highlands (encompassing the central Zagros Mountains) and the lowlands (encompassing southwestern Iran, the provinces of Khuzestan and Fars). Around 4000 BCE the cultures of these two regions were unrelated. More than 100 small villages (at least) dotted the lowlands, seemingly centered in Fars. These villages were roughly the same size; no one village stands out as a major center. In the highlands a new center was established, probably shortly before 4000 BCE. This center was the city of Susa, which would remain important throughout Elamite history. So far about 40 villages have been identified surrounding Susa, but Susa was four times larger than any of these.

From its earliest foundations, Susa was heavily influenced by Mesopotamia, so much so, in fact, that some scholars suggest that it was actually a Mesopotamian colony from 3800 to 3100 BCE. Others say the city was conquered by Mesopotamians; at the very least there was a very significant mingling of Mesopotamian and Susanian culture. This is the time known to Assyri-

ologists as the Uruk period, a period when Mesopotamian culture appears to spread throughout the Fertile Crescent and the period when writing first develops in ancient Mesopotamia. The excavators at Susa found tablets with numerical notations in cuneiform, similar to the Sumerian tablets found at the site of Uruk in Iraq. Some of these tablets were also impressed by cylinder seals, another typically Mesopotamian form of material culture.

From 3100 to 2900 BCE, Mesopotamian influence at Susa lessened. Clay tablets were still used for writing, but Sumerian was replaced by a language that scholars call Proto-Elamite. This language has not been fully translated by scholars, so it is unclear if it actually is a predecessor of Elamite. Whatever the case may be, this Proto-Elamite culture spread throughout western Iran at this time; it is unclear whether this culture originated in Susa and spread outward or came from outside and gradually incorporated Susa.

References to Iran in the Sumerian King List talk of two polities in Iran during what scholars of Mesopotamia call the Early Dynastic period. One of these regions is called Awan, and the other is called Elam. It is unclear what the geographic extent or political makeup of either of these polities would have been. Certainly both Elam and Awan were hostile to Mesopotamia. The Mesopotamian king Sargon, founder of the Akkadian dynasty, campaigned against numerous cities in Iran. His grandson Naram-Sin made a treaty with an Iranian king (whose name is unfortunately not preserved, but he may have been Hita, king of Awan) and incorporated Iran directly into his empire. Akkadian officials moved to Iran, and the region was formally governed by Mesopotamian rulers. Sites dating to this period show a blend of Mesopotamian and Iranian material culture.

After the Akkadian dynasty collapsed, an independent Iran asserted itself, perhaps the first

➤ MESOPOTAMIAN BOOTY FROM SUSAS

Some of the most important artifacts of ancient Mesopotamia were actually recovered by French archaeologists working at the Iranian city of Susa. Taken as booty during the raids of the Elamite king Shutruk-Nahunte, many of these artifacts may not have survived to the present day had they not been seized so many centuries earlier. Two of these artifacts have been especially important for Assyriologists. The Victory Stele of Naram-Sin is one of the most important artifacts of the Akkadian dynasty, describing the elevation of King Naram-Sin to divine status. The Code of Hammurabi, now on display at the Louvre, was also found at Susa. For most modern students of Akkadian this is one of the first texts that they learn to read, and it has been invaluable in reconstructing ancient Mesopotamian social and legal life.

—Kevin M. McGeough

time coalescing as a unified political entity. A king of Awan, King Puzur-Inshushinak, is mentioned in the Susa King List and in other sources as an enemy of King Ur-Nammu of the Third Dynasty of Ur, in Mesopotamia. Puzur-Inshushinak's origins are unclear. He may have been an Akkadian administrator who rose up through the ranks, taking over as king when the Akkadian dynasty collapsed. Or he could have been an Elamite king, outside of the Akkadian sphere of influence, who took the opportunity to conquer Awan when the Akkadian dynasty collapsed. The titles he used to describe himself vary. He claims to have conquered 81 cities in Iran and most certainly unified (at least briefly) the highland and lowland regions. However, he was eventually conquered by King Ur-Nammu, and the earliest unified Elamite polity was incorporated into the Ur III state.

Iran was a willing participant in Ur III governance until about the forty-seventh year of King Shulgi's reign. Starting then (and lasting until the collapse of the Ur III state), a region in Iran referred to as Shimashki struggled against Mesopotamian rule. It is difficult to know the exact extent of Shimashki. Based on indirect Mesopotamian references, it was found in Fars Province but may have extended as far north as the Cas-

pian Sea. As the Ur III military campaigned against Shimashki, the Shimashkians became more unified against this external threat and eventually allied themselves with Ibši-Sin, a Mesopotamian who was himself vying for control of the Ur III state. Susa and environs were retaken under Iranian control, and a loose confederation of Iranian cities formed in order to battle their common Mesopotamian enemy. The later literary tablet, "The Lamentation over the Destruction of Sumer and Ur," records that Elam and Shimashki dwelt in Ur (meaning that they conquered the city of Ur).

The Elamites

The kings of Susa in Iran began calling themselves *sukkalmaḥ* (a Mesopotamian title with various connotations) after the collapse of the Ur III state in Mesopotamia, a collapse that they helped facilitate. They also used a variety of other titles, which scholars do not understand, to describe other government officials. The relative status of the *sukkulmahs* at this time is apparent from their treatment in international correspondence. A letter to the Mesopotamian king Rim-Sin (of Larsa) speaks of "the great king of Elam." Letters from cities in Syria express deference to Elam, referring to the king as "father," a title of respect acknowledging the king as more powerful than the letter writer, as opposed to a sign of a family connection.

Around 1500 BCE, during the Middle Elamite period (1500–1100 BCE), Elamite kings stop calling themselves *sukkulmahs* and start calling themselves variations of “King of Susa and Anshan.” This title was ceremonial and does not necessarily imply that either of these cities were the capitals of Elam at the time. This period of Elamite history is divided into three subdivisions, based on the different ruling dynasties. In the Middle Elamite I period, five different kings rule, with Susa most likely their capital. It is unclear whether or not any of them were related to one another. Most noteworthy of these kings was Tepti-Ahar, who built an elaborate tomb for himself at Haft Tepe, the site where many Middle Elamite I texts came from.

Around 1400 BCE, Igi-halki founded the Igi-halkid dynasty. Texts found at Deh-e describe how various deities gave Igi-halki his kingship. This is a typically Mesopotamian way of justifying a coup d'état, so it is likely that Igi-halki seized power through violent confrontation. A successor of Igi-halki's, King Untash-Napirisha, founded the huge site of Choga Zanbil. Still preserved there today is a massive ziggurat dating to this time, along with temples, a palace, and wall 2.5 miles (4 kilometers) long. Between 5,000 and 6,500 inscribed bricks have been recovered from the site, which certainly was intended as the capital, replacing Susa. There is no evidence for any of King Untash-Napirisha's successors here, so it is likely that Susa became the capital once again after his death.

It is unclear how the Igi-halkid Dynasty came to an end, but from 1200–1100 BCE, the Shutrukid Dynasty ruled Elam. The first of these kings (and the dynastic namesake) was Shutruk-Nahunte. Archaeologists have found much evidence for his activities at Susa, including over

450 bricks inscribed with his name. Shutruk-Nahunte actively engaged in campaigns to subdue cities all over Iran, as attested by his practice of removing stelae from other cities to display in Susa. He treated Mesopotamia in a similar fashion, attacking cities in Iraq and removing their treasures to Susa.

It was these incursions against Mesopotamia that according to the Mesopotamian poem “The Deeds of Nebuchadnezzar I” led to the eventual downfall of the Shutrukids. According to this poem, Shutruk-Nahunte's son, Kutir-Nahunte, removed the cult statue of the god Marduk from the Esagila (an important temple in Babylon), a blatant demonstration of superiority over southern Iraq. Nebuchadnezzar (not to be confused with the Nebuchadnezzar mentioned in the Old Testament who sacked Jerusalem) who ruled the Sealand dynasty of Babylonia during 1125–1104 BCE, prayed to Marduk to return his people to power. Marduk agreed to do so if Nebuchadnezzar brought his cult statue back from Elam. Whatever Nebuchadnezzar's motivations actually were, he did attack Elam, driving the then king of Elam (Hutelutush-Inshushinak) from power. With that, the Shutrukid Dynasty collapsed, and the Middle Elamite III period drew to a close.

■ Introduction: The Origins of Kingship

The first kings came to power sometime after 4000 BCE. With the rise of the first states in Egypt, Mesopotamia, and China and the secondary states that they came into

contact with, political governance centered upon the power of one individual came to be the dominant mode of governing large polities. Throughout the Near East and East Asia, royal rule became

the normative model of governance. Although the nature of kingship varied dramatically from place to place, the essential feature—the rule of the state by a single individual—was common to all of these regions.

Ancient kings have often been called “absolutist” rulers, but this is not entirely accurate. Although it is true that ancient monarchs held substantial authority over their polities, the amount of power varied dramatically from region to region. In actual practice, while the king’s decision-making processes may have been unencumbered by legal limits, the power of the king varied depending on a number of factors including military power, the power of other elites within the states, religious considerations, economic might, and the presence of infrastructure that allowed the monarch to carry out his wishes. Ancient polities governed by kings were more often than not very decentralized. Ancient societies lacked the communication and transportation technologies that are essential for enacting centralized authority.

Ancient kingship was often hereditary but not always. The Sumerian King List from ancient Mesopotamia describes ancient kingship as passing from father to son until the gods remove power from that family and give it to another. A similar situation is described in ancient Chinese accounts. The royal line in Egypt also passed between different dynasties, yet in Egypt the king was seen as the offspring of the gods and held a semidivine status. There are isolated examples of kings from other regions who claimed divine connections (such as Naram-Sin of Mesopotamia), but these are relatively unusual situations for the period.

How kingship arose throughout the Near East, the Mediterranean, and East Asia differs in each individual situation. In most regions, kingship was adopted based on contact with regions that already had a king. Either a king was put into a position of authority by a more powerful state, or a king arose from within the community through a number of possible scenarios. How kingship arose in Egypt and China is a more difficult question, as the institution appears in both locations seemingly out of nowhere.

—Kevin M. McGeough

The Development of Kingship in Egypt

The institution of kingship was one of the defining features of Egyptian culture from the very beginning of Egyptian history. The earliest known king to rule over a unified Egypt was Narmer (ca. 3000, “Dynasty 0”), whose famous commemorative stone palette depicts much of the iconography and ideology that would remain fundamental elements of kingship for the rest of Pharaonic history.

On both sides of the palette discovered at an early temple deposit at Hierakonpolis, Narmer is depicted as a triumphant warrior. On one side he wears the white crown, representing his rulership over Upper Egypt, while on the other side he wears the red crown of Lower Egypt. In one scene, Narmer grasps a defeated enemy by the hair and raises a mace over his head, preparing to smite his captive. The smiting scene would become one of the most enduring images of kingship in Egyptian history. Narmer is also depicted wearing a false beard and a bull’s tail (which would also become standard elements in depictions of kings). Scenes of a bull attacking a city and a falcon holding a captive enemy also appear on the palette; both animals had strong connotations of royalty in Egyptian thought.

Another roughly contemporary depiction of Egyptian kingship at its earliest stage is the mace-head of King Scorpion, which depicts a different but equally important aspect of Egyptian kingship. The preserved portion of the middle register of the mace-head depicts Scorpion in the midst of an agricultural scene carrying a plow. The Scorpion mace-head and the Narmer palette both show fundamental aspects of the Egyptian conception of kingship: the king was both a ferocious warrior who conquered enemies and annexed territory and a nurturing ruler who tended to his land like a farmer.

During the Old Kingdom (ca. 2686–2160), the king was represented as a living god who held supreme authority and was responsible for maintaining the well-being of Egypt by means of his magical potency. At death, the king was thought to join with Re and Osiris and to be magically reborn in the form of his successor.

The unification of Egypt had created a massive and powerful geopolitical entity with great potential for wealth and expansion, but it required a complex bureaucracy and large-scale organization and cooperation to function. The state's resources were poured into massive royal construction projects and public works, which necessitated trade and stimulated Egypt's physical and economic growth through an elaborate redistributive system. All of this was justified by the king's divine status and his role as protector of *ma'at*, or cosmic order.

The Old Kingdom's collapse heralded a period of political decentralization and economic decline during which Egypt was ruled by nomarchs, local administrators who rose to the status of petty kings in the absence of a major central political power. In the following Middle Kingdom (ca. 2055–1650), the nature of kingship had shifted slightly: the Middle Kingdom pharaohs, members of a family from Thebes that had fought its way to prominence and reunited Egypt, were distinctly aware of their roots. The pharaohs of the Twelfth Dynasty (ca. 1985–1773) in particular depicted themselves as far more human than their Old Kingdom predecessors. Literature from the time focuses on the wisdom and beneficence of the king.

In the wake of the Second Intermediate period (ca. 1650–1550), a Theban family once again arose to drive out the foreign rulers who had settled in the Delta (the Hyksos) and reunited the fragmented kingdom. The New Kingdom (ca. 1550–1069) again brought about a shift in the way the king was presented: he was now a warrior fighting not only to protect Egypt but also to actively extend its boundaries. The king was also viewed increasingly during the course of the New Kingdom as an agent of the god Amun (the patron god of Thebes), to whom all of the king's successes in battle were credited. In a popular literary genre of the time, the *Königsnovelle*, the king was presented as a master military strategist who decisively rejected his military advisors' cautious advice in favor of a more radical (but always successful) approach.

During the course of Egyptian history, the gap between kings and nonroyal individuals gradually diminished. This trend had already be-

➤ WOMEN AND KINGSHIP IN EGYPT

Kingship was a fundamentally masculine institution. Although several women exercised sole rule over Egypt during the course of Pharaonic history, only one, Maatkare Hatshepsut (ca. 1473–1458), presented herself as a king, during the middle Eighteenth Dynasty (ca. 1550–1069). Although she made some attempts to feminize the traditional royal titulary and iconography (for example, calling herself “the daughter of Re” rather than “the son of Re”), she eventually chose to simply represent herself as male. Hatshepsut's reign was stable and successful, but her experiment in kingship was rejected by her immediate successors, who excised her name from her monuments and left her out of the official King Lists.

The next three pharaohs of the Eighteenth Dynasty did not promote any women to the office of Great King's Wife, a position that had achieved an immense level of importance with the beginning of the Eighteenth Dynasty. This was perhaps a direct reaction to Hatshepsut's assumption of power, since she had at one time held the rank of Great King's Wife herself. Amenhotep III (ca. 1390–1352) revived the tradition. Nefertiti, the principal wife of Amenhotep III's successor Akhenaten (ca. 1352–1336), was depicted wearing kingly attire and participating in traditionally kingly activities (such as smiting captives) and was even called “Lady of the Two Lands” (a feminized version of a kingly title). However, she apparently never achieved full independent kingship status, as had Hatshepsut.

—Megaera Lorenz

gun as early as the First Intermediate period (ca. 2160–2055), when nonroyal individuals began using traditionally royal funerary practices, such as the use of funerary spells based on the Pyramid Texts and the decoration of the corpse with royal accoutrements (diadems, scepters, and the pharaonic bull tail) to identify the deceased with Osiris, the king of the netherworld. By the early Third Intermediate period (ca. 1069–664), in a curious reversal of this process, royal burials began to strongly resemble the traditional burials of wealthy private individuals, with the same standardized set of funerary equipment and texts.

Powerful nonroyal individuals also increasingly began to take on royal attributes. By the end of the New Kingdom the High Priest of Amun was essentially presenting himself as a pharaoh in Upper Egypt, while Ramses XI (ca. 1099–1069) reigned ineffectually in the north of the country. By the Twenty-fifth Dynasty (ca. 747–656), high-ranking officials were building massive funerary monuments to rival royal burials of any period of Egyptian history.

By the Ptolemaic period (332–30), many of the functions once filled by the kingship now lay in the hands of the priesthood of the major religious institutions of the state. The Ptolemies administered over the country, politically and economically, and depicted themselves as traditional Egyptian pharaohs. However, they ruled in relative isolation in Alexandria, and the traditional institution of kingship became, for most of the populace, increasingly symbolic and esoteric. Although a human king technically occupied the throne, the priests of the Horus cult revered the sacred falcon itself as the earthly manifestation of the divine kingship. One of the most striking signs of how abstract the concept of kingship had become is a series of royal cartouches inscribed on the wall of the Ptolemaic temple at Dendara. Inside the cartouches, where one would expect to find the name of the reigning king, there is only inscribed the word “Pharaoh.”

The Rise of Kingship in Mesopotamia

The early third millennium BCE saw the increasing importance of secular authority at the expense of religious authority within the Sumerian city-states as the need for defense put power into the hands of war leaders. These were probably originally appointed temporarily by the city council but through time gained permanence.

Nevertheless, the ruler governed in the name of the city's deity and had sacred duties, including maintaining the god's shrine with offerings and performing the leading role in religious festivals.

Growing interstate conflict enabled kings to increase and consolidate their power. Kingship came to be vested in dynasties, but the citizens may have selected a king's successor from among his sons or brothers subject to the city god's approval, probably obtained by divination. Misfortunes reflected divine disapprobation, and an unsuccessful monarch could be overthrown.

Each Sumerian city identified itself as the property of its tutelary deity. The prosperity of the city depended on the presence and favor of the city's god, and in turn the god or goddess depended on the service of the citizens, led by their king, the god's representative. Nippur was the city of the god Enlil, who was acclaimed as chief of the gods by the end of the Early Dynastic III period, and Enlil's temple at Nippur became the acknowledged religious center of Sumer. Enlil's approval, given through his priests, was a prerequisite for the success of any city's ruler, and his backing was sought by kings anxious to extend their domains or attack their enemies.

After 2500 BCE individual kings of powerful states began to harbor territorial ambitions, culminating in Sargon's creation of the first empire, of Sumer and Akkad, an integrated state in which authority was centralized in the king's hands and in a newly founded city, Agade. In place of the old Sumerian kings, Sargon and his successors appointed Akkadian governors to administer the individual city-states, backed up by a substantial army. The Akkadian kings nevertheless expressed their authority through traditional roles and titles, invoking the approval bestowed by Enlil through Nippur. Temples still wielded considerable influence through their power to legitimate royal authority, in the name of the gods they served, but the Akkadian rulers gained control over them by appointing members of the royal family and other loyal followers of the regime to fill temple posts. The fourth king, Naram-Sin, claimed to have been invited by the gods to become Agade's patron deity. His elevation to divine status also enabled him to assume the role of tutelary god of the empire itself. Having a divine king as head of state altered the ide-

ology of kingship; nevertheless, even as a god, the king was subordinate to Enlil and therefore still answerable to divine authority.

The years following the collapse of the Akkadian empire saw local dynasties reestablished in many city-states, their ideology consciously recalling earlier days when each city was independent and existed as the estate of its tutelary deity. Within a century, however, the city-states were again united, under the Third Dynasty of Ur (Ur III). Its first king, Ur-Nammu, devoted much time and effort to reestablishing stability, and his son, Shulgi, consolidated the empire. Ur-Nammu instituted major reforms, creating a standing army and reorganizing the economic system, greatly increasing royal power. They created an obsessively efficient bureaucracy in which a vast number of civil servants recorded taxes, tribute, and the yields from state lands, flocks, and herds in minute detail. They ostensibly followed traditional Sumerian political organization, dividing Sumer and Akkad into 20 provinces largely corresponding to the major earlier city-states, often ruled by members of each city's royal house, now governors. However, the Ur III kings circumscribed their power by installing a member of the royal family or some other loyal supporter from outside the province as a military governor to work alongside each local ruler.

The Ur III kings used ideology to win support within Sumer and Akkad, emphasizing their links with the past and their upholding of tradition and their piety and role as divinely appointed protectors of the people. In contrast, beyond this core region they had no need to follow tradition; peripheral lands, to the east and north, were administered by military governors who were granted Crown lands. The Ur III rulers expressed their authority in traditional terms, the king exercising control on behalf of the gods and mediating between them and the people of the land: the accepted role of the city-state's ruler writ large, the whole empire being the estate administered by the king. The relationship between the ruler and the gods became closer when Shulgi proclaimed himself a god. While Ur was their capital, the ancient city of Uruk was the Ur III dynasty's spiritual home, and they claimed kinship with its revered First Dynasty,

➤ SHULGI, THE VIRTUOUS KING

More than 20 hymns as well as inscriptions and other literature celebrate the virtues of Shulgi, the second Ur III king, drawing attention to his place as the descendant of ancient kings, upholder of tradition, and representative of the gods. Shulgi performed the traditional sacred marriage with the goddess Inanna, tutelary deity of the ancient city of Uruk. He promulgated one of the first law codes, laying down rules of conduct and punishments for crime but also setting out the ethical and religious basis for his code and detailing his own reforms. This provided a model that many later kings aspired to follow.

The hymns reveal the benefits that the gods expected Shulgi to bring about when they chose him as king: the prosperity of the country, through both domestic production and the acquisition of foreign treasures; generous support for the gods' shrines, especially that of Enlil; the administration of justice; the enhanced prestige of his capital city of Ur; and the protection of the land against its enemies. In some poems, couched in the first person, Shulgi enumerates his own virtues, including his academic excellence and diligence as a schoolboy. He recounts his bravery and excellent command of martial arts in battle and on the hunting field, where he slays lions to protect his people (both a royal prerogative and a royal duty). His religious virtues include infallibility in divination, superb musical accomplishments, deep piety, the provision of abundant offerings for the temples, and the composition of sublime hymns. He endows schools so that his hymns may be performed in perpetuity. He exhibits supreme wisdom, both in the council chamber and in the law court, promoting righteousness and defending the weak.

—Jane R. McIntosh

whose deeds they glorified by committing to writing the traditional stories of Gilgamesh and his forebears. They undertook extensive restoration and new building in the traditional religious centers, Ur receiving particular attention. In fulfillment of their sacred duty to ensure the prosperity and welfare of their subjects, the Ur III kings undertook many public works, constructing and maintaining canals and roads for irrigation and communications, and regularized many

aspects of life, from the calendar and the official use of the Sumerian language to the standardization of weights and measures.

No later Mesopotamian state attained the degree of control over its dominions exercised by the Ur III dynasty. Nevertheless, from this time onward, sizable territorial states were to be the norm, their extent and power depending on the strength and competence of individual rulers and dynasties. The earlier second millennium saw the rise of competing states centered on Isin, Larsa, Babylon and other cities. With the emergence of Hammurabi's empire, Babylonia became an enduring political entity. Northern Mesopotamia took longer to develop a political identity.

One major change altered the basis of authority in some states and had a wider influence on royal ideology. During the early second millennium many states fell to Amorite sheikhs. In the Sumerian city-states the loyalties of the people and their rulers had always been to their city and its god. Among the nomadic peoples of the west, however, including the Amorites, tribal loyalties took priority over those of place. This for the first time produced states whose basis was ethnic rather than, or as well as, territorial. The ruler's legitimacy now depended on (real or fictitious) descent from earlier kings in addition to the traditional approval of the gods. The earlier ideology was also manipulated to support the new order when, under Hammurabi, supreme divine authority was transferred from Enlil at Nippur to Babylon's god Marduk, henceforth the chief god of the Babylonian pantheon, thus enabling spiritual as well as secular authority to pass to Babylon.

The universally recognized duty of a Mesopotamian king was to ensure the welfare of his subjects: defending them against external threats; promoting prosperity through appropriate construction projects (particularly of irrigation systems), good management of land and resources, and the encouragement and sponsorship of trade and industry; supporting justice; and caring for the most vulnerable members of society such as orphans and widows. To this end some kings issued an edict (*misharum*) cancelling outstanding debts to the Crown. Kings might also fix wages and prices and standardize weights and measures. Rulers also had important ritual duties,

representing the community in making offerings and in some cities taking part in a sacred marriage ceremony. Royal and state success and prosperity were understood to reflect the king's legitimacy and divine approval of his actions; conversely, disasters were attributable to some failure in the monarch's performance of his duties.

Divinity and Kingship— Mesopotamia and Egypt

In Mesopotamia as in Egypt, the institution of kingship had close connections to religion and to the gods. In Egypt, kingship was considered a divine institution, a fundamental part of the world as it was ordered by the gods and with the gods themselves named as the first kings. Although it eventually fell to human rulers to govern Egypt, they claimed divine relationships and qualities to legitimate their reigns and were posthumously transformed into gods. In Mesopotamia, while kingship was thought to have been handed down from the gods and although kings served as the intermediaries between the human and divine worlds, the kings themselves were not typically ascribed divine qualities or worship even after death. Those few kings who declared themselves gods during their lifetimes, most notably from the Akkadian and Ur III dynasties, were atypical in the history of Mesopotamian kingship.

The distinction between the divine office of Egyptian kingship and the humans who filled it was an important one, although it was not widely

recognized until G. Posener's publication on the subject in 1960. At issue is the interpretation of the pharaoh's titles, which identified him both as the falcon god Horus and the son of Re, the Egyptian sun god. These claims of divine embodiment and parentage should not necessarily be read literally but were instead part of the symbolic language of kingship. The pharaoh was superior to all other humans, but while he may have exhibited traits of the deities with whom he was associated, he was generally considered to be subordinate to them. This principle is apparent in Egyptian art, where the pharaoh is depicted as much larger in scale than other humans, emphasizing his superior status, but is rarely shown as a true counterpart of the gods. He may be represented as a child being suckled by a goddess, as a powerful king under divine protection, or in the act of offering gifts to the gods to secure their support of his reign. While the myth of the king's divine birth and essence was more aggressively propagated from the time of the Twelfth Dynasty, the human king's apotheosis generally occurred only after death, when he was united with Osiris.

In Mesopotamia, the question of the king's divinity has been less contentious. Although he was of the highest human status, the king remained a servant of the gods. He ruled only by divine consent, and the success of his reign was dependent on ensuring the gods' continued comfort and goodwill. His investiture was carried out in the temple, and his most important tasks included building and repairing the temples in his territory, which served as the houses of the gods, and making regular offerings of food and other gifts. The king also participated in numerous religious rituals in which he interacted with the divine, including the infamous Sacred Marriage Ceremony. This fertility ceremony, which saw the king engage in intercourse with the goddess Ishtar, possibly represented by her priestess, was performed to maintain the prosperity of the land and its people.

Only a few kings in the history of Mesopotamian kingship asserted their divinity, usually in response to extraordinary circumstances. Naram-Sin of Akkad (ca. 2260–2223) was the first to be deified during his lifetime, likely as a political gambit to consolidate his power over the vast

➤ THE BASSETKI INSCRIPTION

In 1975, a life-sized copper statue of a nude male, preserved to the waist and seated on a circular base, was acquired by the Iraq Museum. Discovered near Bassetki in northern Iraq, this statue not only represents one of the few surviving examples of large-scale sculpture from the Akkadian empire but also offers a rare insight into the propaganda accompanying King Naram-Sin's deification. The inscription on the base records that it is the citizens of Agade who request him as the god of their city, both because of his extraordinary military accomplishments and because he is beloved by the gods.

—Karen Sonik

and unruly Akkadian empire rather than as an exclusively religious statement. This same strategy was adopted by Shulgi (ca. 2094–2047) and his successors, who faced similar political difficulties in their rule over the Ur III empire, but was rarely used in later Mesopotamian history.

China—The Sage Emperors

A sage is a person noted for particularly deep wisdom, rather than merely someone who has acquired much knowledge. Among the ranks of holy people, sages are normally male, and those called sages in English are usually not people of

superior scholarly attainment. Instead, the sages appear in the earliest layers of legends of peoples as human beings specially inspired by the gods to provide for the essential needs of human life, such as agriculture, or the arts of civilization, such as writing. Other, more historically traceable holy people of great wisdom are sometimes also called sages (especially the early rabbis of Judaism in the first two centuries of the Common Era, the hakham, who played a heroic role saving the Jewish faith despite the loss of the Temple). The term “sage” is sometimes restricted, however, to the early legendary creative geniuses who made human existence itself possible. It is interesting to note that this role is often played by mortals inspired by gods, rather than gods come to earth, although sages tend in legend to enjoy surprising longevity and sometimes win immortality.

In Chinese traditional lore, six great sage-emperors, dating their reigns to early in the third millennium BCE, brought the accoutrements of civilization to the land. These enlightened rulers (Fuxi, Shen Nong, Huangdi, Yao, Shun, and Yu) established order in the world and the first three are traditionally considered to be divine. For example, Huangdi, the “Yellow Emperor,” is credited with creating the humanities, writing, the

compass, the pottery wheel, and the Chinese social order in about 2000 BCE. Yu the Great is credited both with controlling the flooding of the Yellow River (making agriculture possible) and with beginning the practice of hereditary rule at a slightly earlier time. Like the Mesopotamian sages, these figures are regarded as human, but at the same time they transcend humanity. The first of the group, Fuxi, who taught the use of the fishing net, domestication of animals, music, and casting oracles, was human—but had the body of a snake. Similarly, Huangdi was human—but came into being spontaneously, and attained immortality at the age of one hundred, ascending to heaven on a dragon’s back. As Confucianism and Daoism developed in China, both religions accepted the sage-emperors as founding “culture heroes.”

■ Introduction: The Dynasties of Egypt

The political history of ancient Egypt provides the framework that historians use to describe Egyptian chronology: the dynasty. There were 32 dynasties in Egypt numbering from 0 to 31 (Dynasty 0 was discovered later, so rather than renumber all of the other dynasties it was given the designation “0”). Each of these dynasties ideally reflects a period of time in which one family of rulers led Egypt. This is only the ideal, since in actual fact the leadership of Egypt was not always as clear-cut as this. Sometimes there were competing dynasties, and sometimes kingship did not pass between family members. Sometimes the breaks between dynasties seem relatively arbitrary; however, the dy-

nastic system of periodization provides a useful standard that all Egyptologists use, and thus it is important to have a broad familiarity with it.

Every Egyptian dynasty is grouped into a larger unit, referred to as either a “kingdom” or a “period.” Generally, a “kingdom” was a time of centralized political authority and stability in Egypt, whereas a “period” was a time of decentralization and possibly competing leadership. This organizational schema implies that Egyptian history was cyclical, vacillating between centralized and decentralized authority. As with the dynastic system, this itself is an oversimplification, but this kind of periodization does provide a useful common framework for Egyptologists.

Understanding Egyptian history as a successive series of dynasties grouped into kingdoms and periods is an ancient practice. Manetho, a Greek historian who wrote during the third century BCE, seems to have established this system. The ancient Egyptians themselves also kept track of their kings in a similar fashion. Examples of these records include the Palermo Stone, the Turin Royal Canon, and the Abydos King List, all of which have survived to the present. Modern historians use a synthesis of all of these sources to reconstruct the historical chronology of ancient Egypt.

What follows is a discussion of the main political events in each of the kingdoms and periods that fall within the time period. For information on the Predynastic period, see the volumes covering the period up to 4000 BCE, and for the Third Intermediate period and the Late period, see the volumes covering the time between 1000 BCE and 300 CE.

—Kevin M. McGeough

The Early Dynastic Period in Egypt

Egypt's Early Dynastic period, circa 3000 BCE, is defined in this essay as encompassing the First through Second Dynasties. The Early Dynastic period marks the change from warring city-states and polities to a developed nation under one rule. The government of Egypt, headed by a semidivine ruler with an elite class of nobility supporting the bureaucratic structure, became established. Writing, having made its first appearance in the pre-dynastic period, had become an elite skill. Foreign trade flourished. Memphis was founded as the economical and political capital of the country.

The division of the history of Egypt into dynasties is based on accounts by the much-later Greek historian Manetho; Herodotus (fifth century BCE) also provides historical details. Additional sources are the Turin Canon from the New Kingdom and the Palermo Stone, possibly from the Old Kingdom, that list the earliest kings' names. Early Dynastic period resources are often diverse and contradictory but provide a good deal of information. For example, the impressions of two seals have been recently discovered

MEMPHIS

According to tradition, King Menes or King Hor-Aha founded Memphis as the capital city of unified Egypt early in the First Dynasty. Memphis grew to become one of the most important cities in the ancient world and, while not always the capital of Egypt, was often a major power. Much of the city's power came from its strategic location, south of the apex of the delta. Thus, it straddled both Upper and Lower Egypt. It was also located along the major east-west trade routes, providing a good economic vantage point as well. Its prominent position along these trade routes and its political importance led to its development as one of Egypt's most cosmopolitan centers. Foreign merchants settled in the city, foreign mercenaries were recruited here, and the arts and religions of foreign lands were accepted here.

—Kevin M. McGeough

in the First Dynasty cemetery in Abydos. The seals, associated with the mortuary buildings of Kings Den and Qaa, list First Dynasty kings. More information comes from thousands of inscribed objects of the First and Second Dynasties found under the Step Pyramid of Djoser.

The First Dynasty comprises eight kings, a conclusion supported by the seal from Qaa, the Abydos King List, and Manetho. Narmer, the first king, may be conflated with Menes, the first king recorded on the Abydos List. Narmer's influence was widespread; his name appears on artifacts throughout Egypt and even Israel. In contrast, his predecessors are minimally represented, with recognition confined to single regions. Narmer thus appears to have become the sole ruler of a unified Egypt. Pharaoh Den, entombed also at Abydos, enjoyed the longest reign of the period, a reign that brought advances in art and burial architecture. During his reign, the king's title of *nsw-bity* ("he of the sedge and the bee") first appeared. Also, an elite cemetery was established in the Memphis region, although royal burials centered in Abydos near the ancestral city of This.

The succession of the Second Dynasty is not as well known. The order and names of the first three kings are documented because one kings'

list agrees with an inscription on a small statue from the period (currently in the Cairo Museum, CG 1). The kings' lists and contemporary artifacts agree on the next two and the last kings, but intervening individuals are too diversely represented to reconcile the evidence.

The Second Dynasty appears to have been a period of unrest in the formation of the state. The first king, Hetepsekhemwy, buried his predecessor Qaa in Abydos. It is possible that his name, which means "The Peaceful One of the Two Powers," is evidence for a rift that Hetepsekhemwy was able to heal. Furthermore, he was interred in a new style of gallery tomb in Saqqara, near Memphis, instead of in Abydos. His successors Raneb and Nynetjer were also buried there. But under the reign of Peribsen, royal burials returned to Abydos. Additionally, Peribsen was titled "The Seth," correlating his divinity with Horus's brother rather than with the traditional falcon god. Many suggest that the change of burial site and title imply continued political unrest. This disorder was contained by the last king of the Second Dynasty, Kasekhemwy. At first appearance in the city of Hierakonpolis, he used the traditional Horus title and called himself Khasekhem, "The Power Has Appeared." Later, he added the Seth animal to the Horus falcon and "wy" to the end of his name: Kasekhem-wy, or "The Two Powers Have Appeared." Scholars believe that this name change and the addition of Seth to his titles demonstrate his role in ending the conflict. Khasekhemwy is buried in Abydos in a vast, complex site with a stone-lined burial chamber. Although large, most royal mortuary constructions were of mud brick with minimal stone elements. This construct is a precursor to the greatest architectural achievement of the first king of the Third Dynasty, the Step Pyramid.

The Old Kingdom

The Old Kingdom (OK) is defined as the roughly 560-year period between the beginning of the Third Dynasty (ca. 2686) and the end of the Sixth Dynasty (ca. 2160). There is little that distinguishes the early OK from the Early Dynastic period (EDP) except for a single remarkable innovation: the development of the royal pyramid complex. The Third Dynasty (ca. 2686–2613) was directly descended from the Second Dynasty and shared the same capital at Memphis. Memphis (ancient Ineb-Hedj), near present-day Cairo, would serve as the capital for the duration of the OK. Nothing is preserved of the OK administrative center itself, so current knowledge of OK Memphis derives from historical documentation rather than archaeological evidence.

The royal and elite funerary complexes and their associated temples are the context from which most of our knowledge of OK history, religion, literature, art, politics, and society derives. Although monumental royal funerary complexes had already been in existence since the EDP, they were primarily composed of mud brick and wood, with some elements in stone. It was during the reign of Djoser (ca. 2667–2648), probably the second pharaoh of the Third Dynasty, that the world's first known monumental stone construction—a funerary complex consisting of a stepped pyramid and a stone courtyard—was built at Saqqara. The courtyard was meant to imitate the hall that the king would have used in life for his Heb-Sed festival, a ritual meant to revitalize his authority and magical potency.

This innovation was credited throughout Egyptian history to Djoser's architect, Imhotep. Although there are few contemporary references to Imhotep, his historicity is not in doubt. His name appears on the base of a dedicatory statue of Djoser. Imhotep was revered as a wise man (and even a deity in the Ptolemaic era) up until the time of the Arab conquest in the seventh

View of the Bent Pyramid at Dahshur, built by the Egyptian king Sneferu (2613–2589 BCE). This structure, an early attempt at achieving a classical pyramid shape without steps, is known as the Bent Pyramid due to the way the angle shifts abruptly near the top. Dahshur is also the site of the Red Pyramid, the king's final (and successful) attempt at creating a true (smooth-sided) pyramid. (Corel)

century CE. His status as a high priest of the sun cult at Heliopolis foreshadowed the eventual importance of Heliopolis as a religious capital in the later OK.

Djoser's two successors, the last kings of the Third Dynasty, both attempted to build pyramid complexes. However, both attempts were abortive, probably thanks to the short duration of their reigns. In the Fourth Dynasty (ca. 2613–2494) the pyramid-building tradition flourished. Beginning with King Sneferu (ca. 2613–2589), the rulers of the Fourth Dynasty built a series of massive stone pyramids along the Giza plateau, near present-day Cairo. In addition to superficial differences in the shape of the pyramids themselves (the Fourth Dynasty pyramids were smooth-sided rather than stepped), the orientation and style of the associated pyramid complex was different from that employed by Djoser, suggesting new developments in religious ideas

associated with the burial of the king. These complexes were the focus of the royal funerary cult, which involved the provision of daily offerings to the soul of the dead king. Members of the royal family and important officials were buried in cemeteries that were incorporated into the pyramid complex.

Several major developments took place in the Fifth Dynasty (ca. 2494–2345). First, the cult of the sun god Re, which had already been increasing in importance throughout the OK, was now raised to the status of a state religion. Heliopolis, the city of which Re was the patron god, became Egypt's religious capital (although the country was still administered from Memphis). Several of the kings of the Fifth Dynasty built sun temples, a tradition started by the first king of the dynasty, Userkaf (ca. 2494–2487). These temples were similar in plan and function to the funerary complexes.

Royal pyramids in the Fifth Dynasty were smaller and more cheaply constructed than their predecessors, and the temple complexes were less standardized. The insides of the pyramids were inscribed with magical texts intended to help the soul of the dead king enter the afterlife and take on divine attributes. These pyramid texts were a royal prerogative in the OK, but they were later adapted for use by nonroyal individuals. A large cache of documents from the pyramid complexes at Abusir has survived, shedding light on the administrative, economic, and religious functions of the state.

While the highest offices in the country had been held almost exclusively by members of the royal family in the Third and Fourth Dynasties, the Fifth Dynasty saw an increasing number of nonroyal individuals gaining office through merit. Administration became less centralized, with the creation of new offices to assist with the administration of the remote parts of the kingdom (for example, the overseer of Upper Egypt, an office created in the late Fifth Dynasty). A larger segment of the population was now able to afford decorated tombs. State religious institutions redistributed land and products donated to the temples or levied as tax as salary for their employees, who probably represented a significant portion of the population.

➤ KHUFU AND THE MAGICIANS

The literary work contained in the Papyrus Westcar (P. Berlin 3033), although set in the Old Kingdom, was probably composed in the Middle Kingdom. The papyrus itself dates to the Second Intermediate period. The text is a series of stories within a story, much like the *Arabian Nights*. The framework for the tales is a day in the court of King Khufu of the Fourth Dynasty. Khufu asks his sons to entertain him with tales of miraculous works by magicians and wise men of the past. Three of his sons tell stories (only one of which is still well preserved), but the fourth, Hordjedef, informs his father that he knows of a contemporary magician named Djedi. Djedi is brought into the court, where he performs several miracles including a prediction of the birth of the first three kings of the Fifth Dynasty. The final tale in the cycle describes the miraculous birth of these three kings, supposedly fathered by Re himself. The importance of this text lies in what it reflects about later traditions surrounding the Old Kingdom and its historical figures. Not only does it hint at Hordjedef's long-standing reputation as a wise man, but it also sheds light on the way the ancient Egyptians viewed the transition between the Fourth and Fifth Dynasties.

—Magaera Lorenz

An important literary genre, the autobiography, came to fruition in this period. These texts, commissioned by officials to be placed in their tombs, describe the individual's official duties and major accomplishments. Along with archaeological evidence, they illuminate the state of Egyptian society and the structure of administration at the time. Many contain references to expeditions for the procurement of foreign goods, such as spices and minerals not found in Egypt. Egypt engaged in friendly trade with Byblos, which provided wood that was crucial to the construction of boats and temple furniture.

In the Sixth Dynasty (ca. 2345–2181) the decentralization of authority continued. The dynasty was plagued with intrigue and succession issues. The second king of the dynasty, Userkara (ca. 2323–2321), may have been a usurper. The biographical text of one official, Weni, describes an assassination attempt against King Pepy I (ca.

2321–2287), Userkara's successor. Local administrators became increasingly powerful. The trend of creating provincial administrative offices that began in the Fifth Dynasty was entrenched by the Sixth Dynasty. A provincial governor, under the nominal control of the pharaoh, ruled every district.

The penultimate king of the Sixth Dynasty, Pepy II (ca. 2278–2184), took office as a boy of 6 years old and ruled for a staggering 94 years. The first half of his reign was relatively successful, marked by a lively policy of foreign trade and numerous expeditions abroad. However, by the second half of his reign, Pepy II's administrative power was virtually nil. Local administrators became increasingly independent. A series of low Nile floods put pressure on the already weakened state. By the time Pepy II died, without an heir, Egypt's central administration had dissolved, leaving an agglomeration of ministates run by petty kings. Pepy was succeeded by a queen, Nitigret (ca. 2184–2181), but her reign was brief, and she was unable to reestablish central authority. While several kings succeeded her, their status was nominal. Egypt would not see unified rule again for another century.

The First Intermediate Period

Following the decline of the Old Kingdom, the First Intermediate period was the earliest major period of political fragmentation since the inception of the Egyptian state. In the traditional scheme of ancient Egyptian history it includes the Eighth Dynasty through part of the Eleventh Dynasty, though more recently some prefer to place the Seventh through Eighth Dynasties in

the Old Kingdom. One by-product of the expanding Old Kingdom bureaucracy was increased wealth and autonomy of those who governed Egypt's nomes (administrative districts). Provincial nomarchs (nome governors) and high-level officials initially were drawn from the ranks of the governing elite, who were buried in royal cemeteries of Memphis. By the late Old Kingdom such officials had, by their own devices and through adjustments implemented by the state, aligned themselves more permanently with their home regions, where they were buried in increasingly elaborate tombs in local cemeteries. High positions were passed through family instead of by royal appointment. Such independence amid the dissolution of national authority led to competition for regional dominance and infighting. Much detail of this period derives from the tomb inscriptions of these nomarch families rather than comparatively sparse royal records.

Historical sources indicate that the Seventh through Eighth Dynasties continued to rule from the Old Kingdom capital at Memphis. The Seventh Dynasty is barely documented and widely treated as fiction. The 70 rulers cited by the ancient historian Manetho as having ruled in a mere 70 days is regarded rather as a statement by later generations about the diminished authority of kingship. If there were claimants to the throne, their reigns were very brief and their influence very slight. The Eighth Dynasty is only slightly less obscure. Up to as many as 18 kings can be recognized in king lists, but archaeological remains are scarce. Some royal decrees survive, while the only substantial royal burial monument located is a small pyramid of Qakare Ibi at Saqqara. Some Eighth Dynasty kings used the throne name of Neferkare, probably to affiliate with late Sixth Dynasty king Pepy II, who had also employed this name.

A destabilizing influx of Asiatic groups into the delta may have contributed to a loss of the Memphite power base, but kingship found new executors near the Fayum region at Herakleopolis with the Ninth through Tenth Dynasties. Of the approximately 18 names assigned, about 5 are well confirmed: 3 kings named Khety (1 of whom founded this dynasty), another named Neferkare, and 1 named Merykare. Though the

➤ CAUSES OF COLLAPSE—SETTING THE STAGE FOR AN INTERMEDIATE PERIOD

Many explanations have been advanced for why the Old Kingdom succumbed to civil unrest in the First Intermediate period. Some have blamed the collapse on the unchecked growth of provincial government, but this is unlikely to have been the sole cause. It may have been due in part to the fact that the last king of the Old Kingdom became too old to successfully rule. (Sources indicate that Pepy II may have reigned for more than 90 years.) Any viable male heirs may have predeceased him, and the dynasty was brought to a close with the rule of Queen Nitocris. The late Old Kingdom experienced a series of lower Nile inundations that would have drastically affected agricultural productivity and food surpluses. The state's inability to assist during a famine would have severely undermined public confidence to the favor of local officials who could independently offer relief.

—Nicholas S. Picardo

full extent of Herakleopolitan rule in northern and Middle Egypt at any one time is unclear, independent competition and alliances among southern nomarchs produced challengers, such as the Eleventh Dynasty based at Thebes. Though tradition traces this dynasty back to an ancestor named Nebhepetre, the first documented figure to consolidate power in the south was Shertawy Intef I. A protracted period of conflict between allies of the Herakleopolitan north and the Theban south followed, with fighting concentrated north of Abydos into Middle Egypt under a significant military push by Wahankh Intef II. Following a third Intef, Nebhepetre Mentuhotep successfully put down the Herakleopolitans. Claiming rule of a unified Egypt, he embarked on a program of reconstruction and began to usher in the Middle Kingdom.

The Middle Kingdom

After the instability of the First Intermediate period subsided with the reunification of the country under Nebhepetre Mentuhotep, the stage was set for a period often considered the classical age of ancient Egyptian culture, the Middle Kingdom (late Eleventh Dynasty–Thirteenth Dynasty, with a tendency to include the Fourteenth Dynasty). As a period during which a higher proportion of the population had appreciable economic resources and expanded access to religious knowledge, it is also sometimes known as an Age of the Middle Class. Sankhare Mentuhotep continued the Eleventh Dynasty's program of restoration begun by Nebhepetre, but by the time of his successor, Nebtawyre Mentuhotep, a concentration of efforts on their native Upper (southern) Egypt had led to a slide in control of the country as a whole. The first king of the Twelfth Dynasty, Amenemhat I, was likely the vizier of this name who had conducted a quarrying expedition for Nebtawyre. He initiated an era that, while reviving some Old Kingdom royal models, also took novel approaches to rule that brought Egypt to new heights of power and cultural achievement.

Amenemhat I presented himself as the bringer of a renewed era, as reflected in his choice of the royal title "Repeater of Births." His most drastic move, the establishment of a new capital city near Lisht, shows an attempt to overcome the failures of his south-focused predecessors and left no doubt about his intentions. He named the city (Amenemhat-) Itj-Tawy, meaning

"Seizer of the Two Lands." Southern roots are evident through the Twelfth Dynasty, however, in the start of the gradual rise of the Theban god Amun to the status of favored state deity. As a response to the influx of foreign peoples into Lower (northern) Egypt from the Syro-Palestinian region across the Sinai Peninsula, a cause of disruption during the First Intermediate period, Amenemhat commissioned the Walls of the Ruler, a defensive project known only from texts that likely included forts.

If Middle Kingdom literary texts such as The Instructions of Amenemhat I and the Tale of Sinuhe are believed, Amenemhat I was assassinated by members of his own inner circle, and his son Senwosret I rushed back to Egypt from a Libyan expedition to assume the kingship. The groundwork having been laid, Senwosret brought the Twelfth Dynasty to its first apogee. Reapportioning the administrative makeup of nome infrastructure, he tightened the links between the central government and the provincial nobility. Trade and resource-gathering expeditions resumed with renewed intensity, and military exploits were directed at all of Egypt's foreign neighbors. Lower (northern) Nubia was for the first time subjected to permanent occupation of Egyptian forces when Senwosret constructed a network of defensive fortresses concentrated at a new southern frontier north of the Nile River's Second Cataract. Egypt's traditional border was the First Cataract at Aswan. Among the monuments erected or restored under his ambitious building program was the first temple at Karnak.

Under Pharaoh Amenemhat II, successful raids into Palestine are recorded, but the following relatively short reign of Senwosret II experienced a constriction in trade and military activity and a reduction in the scale of domestic endeavors. Notable is the site of Kahun (aka el-Lahun/Illahun), where a state-planned community was founded near Senwosret II's pyramid to accommodate his mortuary cult. Some point to this town's grid plan and stark house-size distinctions as architectural representations of Middle Kingdom social structure.

Senwosret III, who located a similar town of his own at Abydos, relieved some of the downward trends of his immediate predecessors. Nomarchs, local governors in the provinces who

were previously conspicuous agents of Egypt's administrative system, fall out of the record. A noticeable expansion of central state bureaucracy followed. At least one area of Palestine was annexed by Egypt, and a series of very harsh campaigns ventured into Nubia to check growing Kushite power beyond the Third Cataract at Kerma. Senwosret's exploits were commemorated on stele inscriptions at Nubian fortresses. He reinforced the occupation by expanding fortresses and adding new ones between the Second and Third Cataracts, taking firm hold of the whole Second Cataract region in the process. He also shifted the staffing of forts from rotating garrison troops to permanently stationed personnel (eventually to include their families).

By contrast, the reign of Amenemhat III was not one of large-scale military pursuits, though he maintained the advancements of his father in both foreign and domestic affairs. His times are characterized by prosperity with a focus on procuring natural resources and building projects. Amenemhat also worked to boost Egypt's internal productivity by reclaiming significant tracts of Faiyum land for farming, approaching the task more intensively than previous efforts starting with Senwosret II. Additional Palestinian expeditions occurred under Amenemhat IV's relatively brief rule. The lack of a suitable heir brought the female pharaoh Sobeknefru to power, but the historical record is fairly quiet on details of this final reign of the Twelfth Dynasty.

The transition from the Twelfth Dynasty to the Thirteenth Dynasty was marked by little change beyond the ruling family itself. Stable at first, a pattern of decline in the power and prestige of kingship led to very rapid successions of kings. Over 60 king names are on record for a period 100–150 years long. Powerful families vying for control—and from whose ranks kings were put forward—became the real political forces in Egypt rather than the office of king itself. Partly contemporary with the Thirteenth Dynasty, an obscure set of kings mostly of local origin in the delta comprised the Fourteenth Dynasty. This group reflects the emergence of regional power bases in Egypt that would characterize the situation of the following Second Intermediate period.

—Nicholas S. Picardo

➤ THE CONUNDRUM OF COREGENCY IN THE MIDDLE KINGDOM

Several Middle Kingdom kings may have adopted a policy of coregency by which a living king named his successor to rule at his side to ensure a seamless transition of power after his death. The impetus for this move might have come under Senwosret I as a response to the assassination of his father and predecessor Amenemhat I. Official documents often record both a calendar date and the year of the current king's reign. Inscriptions listing the regnal years of two consecutive kings at once are interpreted by many as evidence of coregencies. However, even in what at first appear to be clear cases of overlapping reigns, upon further review other scholars feel that sources are still too ambiguous to argue in favor of coregencies in the Middle Kingdom. This practice has repercussions for the modern historian because overlapping reigns affect the chronology of the period. Thus, the field of Middle Kingdom studies endures an ongoing debate over whether a high versus low chronology is appropriate. Coregencies are better documented and less contentious in other periods, such as the New Kingdom.

Second Intermediate Period

The Second Intermediate period (1650–1550 BCE) marks an era in which Egypt experienced less centralized control and political unity than

> TEL ED-DABA

Tel ed-Daba is a site in the northeast corner of the delta along the Pelusiac branch of the Nile River. It has been identified with ancient Avaris, the capital of the Hyksos kingdom in Egypt, and with the southern part of Piramesse, the famous Rameside capital of Egypt that many have equated with the biblical town of Raamses. In ancient times it possessed an excellent natural harbor and due to its position was a key location for controlling both maritime and land routes into Egypt from the Near East. The site grew rapidly from a small village in the Tenth Dynasty to giant proportions during the Ramesside era.

—Kerry Muhlestein

was typical. Since the lack of political cohesion and power came about slowly, it is difficult to pinpoint exactly where on the continuum of entropy an intermediate period began. The Thirteenth Dynasty began with a strong country and a stable government. However, over time the dynasty lost stability and power and as a result lost the output of monumental architecture, literature, documents, and cultural expressions that usually accompanied periods of prosperity and power. Since the Egyptians stopped producing the types of artifacts that preserve historical data, it is much more difficult for Egyptologists to reconstruct what went on in this period. Thus, it becomes very difficult to understand the processes that brought about the decline or the resulting conditions.

Concomitant with the waning power of the Thirteenth Dynasty and its subsequent withdrawal to southern Egypt, the Levantine Hyksos, who had taken up residence at Avaris (Tel ed-Daba) in the northeastern Delta, grew in power and wealth. Hence, it may have been inevitable that they would replace the ephemeral kings of the later Thirteenth Dynasty as rulers of northern Egypt. Egyptian tradition holds that the Hyksos took over the country via military conquest, but with only meager archaeological evidence supporting this, most Egyptologists have adopted a more nuanced view of the takeover. It seems likely that the Hyksos employed economic and

political endeavors combined with military means (perhaps including chariots, not yet introduced into Egypt at the time) to assume rulership, first in the north and eventually controlling the entire country. This marks the first time in Egyptian history that the country was ruled by foreigners.

The Hyksos ruled the country with a combination of Egyptian and Levantine methods. They adopted Egyptian customs, officials, trappings, and titulary, styling themselves as Egyptian rulers. Yet they maintained several Semitic traits, including the employment of a vassal system of government. During a period of roughly 100 years, the powerful Hyksos kings ruled over kinglets or governors of the various areas of Egypt and probably southern coastal Palestine as well. It is apparent that they even dominated Thebes in southern Egypt, although it is difficult to say to what extent. They also controlled areas south of Thebes and engaged in a lively trade with Kush (Nubia) and the Levant. The most powerful of the Hyksos kings were Khayan and Apophis, the latter ruling for nearly 40 years.

The final phase of the Second Intermediate period was marked by wars between Thebes and the Hyksos. As Kamose, a Theban Seventeenth Dynasty ruler, records the story, the rulers of Thebes rebelled against their status as vassals and waged war with their foreign overlords. Seqenenre Taa fought against Apophis, his mummy's multiple head wounds revealing that he died in battle. The war was continued by Kamose, and eventually the Hyksos were ousted from the country by Ahmose, first king of the Eighteenth Dynasty, who not only expelled the foreigners from Egypt but also besieged them in their Palestinian stronghold of Sharuhén.

The Early New Kingdom— Consolidation and the Beginnings of Empire

The Egyptian New Kingdom (Eighteenth Dynasty through Twentieth Dynasty, ca. 1569–1081 BCE), often referred to as the empire period, began with expulsion of the foreign Hyksos invaders, who had ruled the country for more than ten years (the so-called Second Intermediate period), following the collapse of the preceding Middle Kingdom. The liberation of Egypt, which began with conflict between a native Egyptian dynasty at Thebes in the South and the Hyksos seat of power at Avaris in the delta, was completed by Ahmose I (r. 1569–1545). Ahmose's forces expelled the Hyksos overlords, pursuing them as far as Sharuhin in southern Palestine and re-establishing Egypt's military and economic foothold in the Levant. By the end of Ahmose's reign, large-scale monumental construction projects had begun again, financed to a large degree by the influx of silver, gold, and other commodities from the Levant and Nubia.

Amenhotep I (r. 1545–1525) succeeded his father Ahmose and enjoyed a largely peaceful and prosperous reign. He erected a temple at Egypt's southern frontier in Nubia and appointed a man named Turi as viceroy over the southern provinces. Amenhotep also consolidated Egyptian control over the oases in the western desert and the turquoise mines of Serabit el-Khadim in the Sinai. The king's tomb has not been discovered, but his posthumous association as patron and founder of the workmen's village of Deir el-Medina, which housed the craftsmen who built the royal tombs in the Valley of the Kings, suggests that he might have initiated construction at that site as well.

Amenhotep I had no surviving male heirs, so the throne fell to Thutmose I (r. 1525–1516), who does not appear to have been directly related to the preceding royal family. His reign initiated the so-called Tuthmosid line of kings, which would control the Egyptian throne for the majority of the Eighteenth Dynasty. Thutmose I began the expansion of Egypt's northern frontier into Syria, pushing as far as the Euphrates River in the vicinity of Carchemesh, where he erected a commemorative stele. This previously unparalleled

northeastern expansion brought Egypt into direct conflict with the Hurrian kingdom of the Mitanni for the first time. On the southern frontier, Thutmose pushed Egyptian domination as far south as the Third Cataract, incorporating both Lower/northern Nubia (Wawat) and Upper/southern Nubia (Kush) as provinces of Egypt. Back at home, building projects were undertaken throughout the country, including a major renovation of the temple of Amun at Karnak.

In addition to the great expansion of the Egyptian empire, the early Eighteenth Dynasty also witnessed considerable changes in the religious sphere. A new kind of royal tomb, cut into the base of the cliffs in the Valley of the Kings, became the standard funerary monument, replacing the earlier royal pyramids of the Old and Middle Kingdoms. In addition, the already rich genre of Egyptian religious literature was further enhanced with the introduction of texts such as the *Amduat* and *Litany of Re* into the decoration of royal tombs, while the *Book of the Dead* gained popularity in the burial equipment of private persons and lesser royalty. Finally, the god Amun assumed a position of preeminence in the Egyptian pantheon as "King of the Gods" due in large part to the patronage of the early Eighteenth Dynasty kings, who hailed from the god's main cult center at Thebes.

The Early New Kingdom— Hatshepsut, the Female King

Thutmose I was succeeded by a relatively minor king, Thutmose II (r. 1516–1504). During his reign, Thutmose II managed to suppress uprisings in Lower Nubia and Palestine and also elevated his half-sister Hatshepsut to the position of great royal wife. At the time of his death,

Statue of Hatshepsut, dressed in the regalia of a king, at her mortuary temple at Deir el-Bahri. (Dale Gillard)

Thutmose II and Hatshepsut had produced no male heir, and so the crown fell to a son by a minor wife of the king. The new king, Thutmose III (r. 1504–1452), came to the throne as a child. Practical matters of state fell to his stepmother and aunt Hatshepsut, who served as regent in his stead.

By the second or third year of Thutmose III's reign, Hatshepsut assumed complete control of the country and had herself crowned as king of Egypt, assuming the full titulary and regalia associated with the traditionally masculine ruler. Only as king was Hatshepsut (r. 1502–1482) able to fulfill the cultic and mythological roles ex-

pected of the Egyptian ruler, who was believed to be the bodily son of the sun god. To help legitimize her position as the rightful ruler of Egypt, Hatshepsut commissioned the decoration of her mortuary temple at Deir el-Bahri with a series of scenes depicting the god Amun in the guise of Hatshepsut's father Thutmose I, who presents his daughter as his legitimate successor to the Egyptian gods and the royal court. Of course, no such ceremony ever took place, but the decoration of the temple effectively revised history in Hatshepsut's favor, at least for a time.

Hatshepsut's reign was a peaceful one. Her most enduring accomplishment was not a military victory but instead was a grand expedition to the land of Punt in order to procure exotic goods such as incense and ebony for use in the temple of Amun at Karnak. Upon her death, the throne again fell to Thutmose III. The king, now a young man, ultimately embarked on an extensive campaign against the monuments of his stepmother, usurping inscriptions she had carved and destroying images of Hatshepsut herself, thereby erasing the memory of her rule.

The period of Thutmose III's sole reign, beginning around 1485 BCE, faced an immanent crisis abroad. Because of Hatshepsut's largely pacifistic foreign policy, the kingdom of the Mitanni had managed to wrest control of Syria and much of Palestine from Egyptian hands. To counter this threat, Thutmose III embarked upon an extensive series of military campaigns intended to push back the Mitannian invaders. Ultimately, the king was able to reassert Egyptian control all the way to the borders of Mitanni itself, where he erected a commemorative stele on the banks of the Euphrates alongside that of his grandfather, Thutmose I. By the 33rd year of his reign, Thutmose III had established Egypt as the pre-eminent power in the ancient world, and foreign tribute began to flow in from the kings of distant Babylon, Assyria, and Hatti.

The Early New Kingdom— The Height of Empire

Amenhotep II (r. 1454–1419), the son of Thutmose III, was officially named as the king's heir shortly before his death. The new ruler quickly established a reputation for personal strength and brutality toward foreign dissidents. Uprisings in Syria, facilitated by Mitannian aid, were swiftly crushed, and the carcasses of seven rebel princes—supposedly killed by Amenhotep himself—were shipped back to Egypt and Nubia to be placed on display as gruesome reminders of the king's military prowess.

Following the death of Amenhotep II, a lesser prince assumed the throne as Thutmose IV (r. 1419–1410). The specific circumstances behind Thutmose IV's accession remain unknown. According to the propagandistic Sphinx stele, it was the sun god Horemakhet-Khepri-Re-Atum who cleared the young king's path to the throne in return for removing the sand that covered the great sphinx at Giza, which was believed to be an image of the god.

Probably already during the reign of Amenhotep II, Egypt's old foes, the Mitanni, had found themselves caught between the unassailable might of the Egyptian empire to the south and the rising power of the Hittites to the north. The Mitanni eventually made overtures of peace toward Egypt, culminating in a treaty between the two countries. The treaty was sealed by the marriage of a daughter of the Mitannian king Artatama to Thutmose IV as a minor wife, thus setting a precedent that would be followed with great zeal by his son and successor, Amenhotep III.

Amenhotep III (r. 1410–1372) inherited an empire at the height of its power. In the realm of foreign relations, he proved himself to be an unparalleled statesman, strengthening ties with Mesopotamian kings eager to exchange their princesses and other tribute for precious Egyptian and Nubian gold. In Egypt itself, Amenhotep embarked upon a building campaign the likes of which had never been seen. Old temples were refurbished and expanded, and new tem-

ples were built from one end of the country to the other including the king's own mortuary complex, the dimensions of which outstripped even those of the great temple of Amun at Karnak. In addition to numerous new endowments to the cults of Egypt's many gods, Amenhotep III initiated a new focus on his own deification as the living earthly embodiment of the solar disk. This development would have a profound effect on the religious philosophy of his son, Amenhotep IV.

The Early New Kingdom— The Heretic King and the End of the Eighteenth Dynasty

Amenhotep IV (r. 1372–1355) assumed the throne upon his father's death, initially continuing the building projects that the latter had begun at Karnak while also participating in the traditional cults, including that of the god Amun. However, by his fifth regnal year Amenhotep IV had begun construction on a new capital city in Middle Egypt to be known as Akhetaten, "the Horizon of the Solar Disc." At the same time, the king changed his name from Amenhotep ("Amun is satisfied") to Akhenaten ("Effective one of the Solar Disc") and began an iconoclastic campaign against the images and name of the state god Amun in favor of the sole worship of the solar disc. This episode is now known as the Amarna

➤ AKHENATEN, THE RELIGION OF THE DISK, AND THE ART OF AMARNA

King Amenhotep IV, better known as Akhenaten, instituted the first known religious revolution in history. Akhenaten's new religion was personally established by the king as a reaction against the traditional gods of Egypt in general, although its most strident iconoclastic policies were directed against the powerful cult of Amun and his priesthood specifically. According to Hornung, the new religion took focus away from the traditional Egyptian pantheon and the entire cycle of myths relating to the nocturnal journey of the sun as well as the experiences of the dead in the hereafter. In their place, Akhenaten presented the visible manifestation of the sun god—his disk, or *aten*—as the only object of worship. Furthermore, only Akhenaten, the son of the sun, was permitted to worship the disk itself. For the individual Egyptian, Akhenaten assumed the role of god, with his wife Nefertiti as divine consort.

One particularly visible aspect of the changes undertaken during this so-called Amarna heresy was a new style of official art. No longer were the king and his family depicted according to the traditional canon of Egyptian representation. Instead, they were shown as grotesque androgynous caricatures with distended bellies and pendulous breasts on male and female alike, great oblong heads balanced precariously atop sticklike necks, and overly generous lips and eyes. In modern times, speculation has often arisen regarding the possibility that Akhenaten may have suffered from some sort of congenital disease, such as Babinski-Fröhlich or Marfan syndrome, and that the resultant deformities might have provided the template for his new artistic style. More recently, scholarly opinion has swung the other way, noting among other things that

Relief depicting the Egyptian pharaoh Akhenaten with his wife Nefertiti and their children, sitting under the Aten—the divine sun disk. (Ruggero Vanni/Corbis)

Amarna art was itself constantly evolving. By the end of the reign, a mature, less grotesque style had replaced the more disturbing representations of Akhenaten's earlier reign. On the biological level, it has also been noted that disorders such as Babinski-Fröhlich tend to produce sterility, while Akhenaten was known to have fathered numerous children. Instead of a biological rationale, it now appears that Akhenaten sought to incorporate into himself certain iconographic elements of traditional Egyptian fertility gods such as Osiris and Hapy. Because these gods had no place in Akhenaten's new religion, the life-giving bounty they represented was transferred onto the person of the king as the sole provider for mankind through the gifts of his divine father, the solar disk.

—Joshua Roberson

period, after the modern name given to the ancient site of Akhetaten.

Akhenaten died in his 17th regnal year with no male heir and was succeeded by an extremely short-lived and ephemeral king known as Smenkhare (probably ruled ca. 1355). After the disappearance of the latter ruler the throne passed to the young Tutankhaten, who would shortly change his name to Tutankhamun (r. 1355–1346). This change was only the first of many actions,

including the opening of temples closed by Akhenaten and the reinstatement of their priesthoods, that were meant to restore the place of traditional Egyptian religion in the wake of the perceived heresy of the rebel king. Tutankhamun died after a brief reign, around the age of 19. With no clear successor to the throne, Tutankhamun's widow Ankhsenamun took an unheard-of course of action and wrote to the king of the Hittite empire, requesting that they

send a prince to become her husband and the new king of Egypt. Initially suspicious, the Hittite king Suppiluliumas eventually dispatched his son Zananza to Egypt, but the prince was killed en route, souring Egyptian-Hittite relations for many years to come. After the Zananza affair, the throne passed briefly to Tutankhamun's elderly vizier Ay (r. 1346–1343).

The last king of the Eighteenth Dynasty, Horemheb (r. 1343–1315), was a commoner who had served as a general of the Egyptian military under Tutankhamun. During his 27-year reign, Horemheb built prolifically, kept the Hittite empire at bay, and maintained the stability of Egypt's northern border. In addition to his own considerable efforts at restoration following the Amarna heresy, Horemheb also usurped many monuments erected during the reign of Tutankhamun. Subsequent generations would remember him as the first legitimate king following Amenhotep III.

The Later New Kingdom— The Nineteenth Dynasty

The last king of the Eighteenth Dynasty, Horemheb, died with no male heir, instead naming his general and vizier Piramessu, later Ramses, as his successor. The brief one-year reign of Ramses I

(r. 1315–1314) inaugurated a new line of kings for whom the so-called Ramessid period of the later New Kingdom (Nineteenth–Twentieth Dynasties) is named. Ramses I was succeeded by his son, Seti I (r. 1314–1304), whose reign was characterized by a clear desire to restore the military and cultural glory of Egypt to the heights of the early Eighteenth Dynasty and to eliminate the last traces of the Amarna heresy.

In the first year of his reign, Seti conducted military expeditions to the Sinai and Gaza, tightening Egypt's control over the borderlands before pushing on through Canaan and into Lebanon. By the second year of his reign he had moved as far north as Qadesh, subdued an uprising of Libyan tribesmen from the western desert, and fought with apparent success against the Hittites for control of northern Syria. Around this same time, the royal residence was moved northward to the ancestral home of Seti's family in the delta, near modern Qantir and the ancient Hyksos capital of Avaris. Seti I also embarked on a number of building campaigns, paying particular attention to the temple of Amun at Karnak and the cult center of Abydos in Middle Egypt, where he constructed his own mortuary temple and an enormous cenotaph, or false tomb, for the local god, Osiris.

Ramses II (r. 1304–1237 BCE), often referred to in modern literature as Ramses the Great, served as coregent in the last years of his father Seti's reign before assuming the throne. His 67-year reign was the second longest in all of Egyptian history, surpassed only by Pepy II of the Sixth Dynasty. The new king's first military campaign resulted in the capture of Hittite-controlled Amurru, which extended Egyptian dominance as far north as Ugarit. This expansion brought down upon Egypt the full might of the Hittite Army, culminating in the famous Battle of Qadesh. The events of this battle were recorded as a great victory for Egypt, as recounted on the walls of temples at Abydos and Karnak. In reality, the Egyptian Army was divided by a surprise attack. Ramses was able to rally his troops, preventing their total destruction, but Amurru was lost to the Hittite Army. Fighting continued in Syria-Palestine for several more years until Hatti, under pressure from its protracted conflict with Egypt as well as territorial squabbles with

Assyria and dynastic troubles at home, finally agreed to a peace treaty in year 21 of Ramses II's reign. The newly forged friendship between Egypt and Hatti would last until the end of the Hittite empire. With the threat from the north removed, Ramses was able to concentrate most of the remainder of his reign on his building program at home and in Nubia. His efforts as a builder would prove to be unrivaled in terms of sheer volume, but the quality of stonework and relief carving also declined dramatically during this time. Nevertheless, many of the most famous monuments in Egypt, including the massive rock-cut temple at Abu Simbel and the so-called Ramessesum mortuary temple at Thebes, stem from this period, while countless stelae, statues, and temple inscriptions of previous kings were also usurped in Ramses's name. During the course of his reign, Ramses II outlived 12 of his own sons before naming his 13th, Merneptah, as his successor shortly before his death at around the age of 90.

Merneptah (r. 1237–1226) proved to be an extremely effective and powerful leader in his own right. He maintained Egypt's friendly diplomatic stance with the major powers to the northeast—Hatti, Ugarit, and Amurru—and even delivered shipments of grain to the famine-afflicted Hittite king in accordance with the alliance forged by his father. However, a new military power had set its sights on Egypt; a coalition of wandering tribes from the Mediterranean and Black Sea areas known as the Sea Peoples had forged an alliance of their own with the nomadic Libyans, who had long been a thorn in Egypt's western flank. The Sea People–Libyan coalition planned a massive assault that finally struck at the fields of Perire in the western delta in Merneptah's fifth regnal year. Historian Colleen Manassa argues that through the skillful deployment of archers, who were intended to break the ranks of the coalition's close-combat infantry, Merneptah was able to crush the invading army. According to the Egyptian records, some 6,000 enemy fighters were slain and 9,000 taken prisoner, securing Egypt from further Sea People incursions for more than 20 years.

The remaining years of the Nineteenth Dynasty were characterized primarily by short-lived reigns and constant dynastic struggle. Amen-

messe (r. 1226–1221), a minor son of Ramses II, usurped the throne briefly before being deposed by Merneptah's son and legitimate heir, Seti II (r. 1221–1215). Following the latter king's death, his young son Siptah (r. 1215–1209) became king, but the actual power lay in the hands of Siptah's mother and regent, Queen Tawosret, and her Syrian adviser, Chancellor Bay. Like Hatshepsut before her, Tawosret (r. 1209–1201) eventually assumed a full royal titulary and, following the early death of her son, carried on as sole king for perhaps two more years. Her death marked the end of the Nineteenth Dynasty.

The Later New Kingdom—The Twentieth Dynasty

Not long after Tawosret's death, the throne passed to a man of obscure origins named Setnakht (r. 1200–1198 BCE), who became the founder of the Twentieth Dynasty. Following his brief reign, Setnakht was succeeded by his son, the last great ruler of Egypt's New Kingdom, Ramses III (r. 1198–1166 BCE). Ramses III very deliberately modeled his reign on that of his illustrious predecessor and namesake, Ramses II, whom he copied in everything from his royal titulary to the design and decoration of his mortuary temple. These included representations of the earlier king's battle with the Hittites at Qadesh. Militarily, Ramses III was again faced with

the crisis of foreign invasion. In the 20 years since their defeat at the hands of Merneptah, the Libyans and Sea Peoples had consolidated their strength and again set their sights on the rich lands of Egypt. The Libyans attacked in two waves, six years apart; both were crushed, and the survivors were taken as prisoners of war and incorporated into the Egyptian army as mercenaries. The Sea Peoples, in collusion with Philistines and other groups, struck in the period between the two Libyan invasions during Ramses' eighth regnal year. This invasion was also defeated, the survivors taken prisoner and incorporated into Egyptian service as mercenaries. With many thousands of nomadic Libyans and Sea Peoples taken as prisoners of war together with their families, the Egyptians began a policy of massive resettlement, placing their former enemies in colonies throughout the delta and as far south as Middle Egypt, where they quickly became acculturated into Egyptian society. The remainder of Ramses III's reign was spent in relative peace engaging in numerous construction projects throughout the country. However, corruption in the administration, economic difficulties, and domestic strife heralded the country's waning fortune. Finally, a conspiracy hatched by a minor wife, Tiy, with the intent of installing her son Pentaweret on the throne ended in the death of Ramses III. Ultimately, Tiy and Pentaweret were arrested, along with numerous other conspirators, and sentenced variously to execution, forced suicide, amputation of noses and ears, or, in one case, a stern reprimand.

The remainder of the dynasty was marked by a rapid succession of kings descended from Ramses III. Three of his ten sons became kings

themselves: Ramses IV (r. 1166–1160), Ramses V (r. 1160–1156), and Ramses VII (r. 1149–1141). The latter two rulers both died without male heirs, so the throne went to their respective uncles, Ramses VI (r. 1156–1149) and Ramses VIII (r. 1141–1139). The last three rulers of the New Kingdom—Ramses IX (r. 1139–1120), Ramses X (r. 1120–1111), and Ramses XI (r. 1111–1081)—were beleaguered by constant economic crises, famine, corruption, and strife among the necropolis workmen at Deir el-Medina, plundering of the royal tombs, constant incursions of Libyan raiders from the west, and a rebellious Nubian viceroy from the south. Coupled with these factors was a steady decline in respect for the office of the Egyptian king, both domestically and abroad. By the end of Ramses IX's reign, the king had become little more than a figurehead from his residence in the north, while the high priests of Amun at Thebes assumed greater power, eventually claiming the insignia and epithets of kingship for themselves. With the death of Ramses XI, the Twentieth Dynasty and the once great New Kingdom finally drew to a close.

■ Introduction: The Mesopotamian States

Unlike Egypt, Mesopotamia (ancient Iraq) was rarely a unified state. Mesopotamian political history is a history of constantly changing political entities, sometimes as small as a single city or tribe and at other times encompassing the entire floodplain between the

Tigris and Euphrates rivers. Over the 3,000 years that span this era, numerous governing systems were used and abandoned in ancient Mesopotamia and included systems that some have argued to be primitive democracies (or primitive communal governments depending on the particular

scholars ideological outlook!), kingdoms governed by a ruling family, and formal bureaucratic states. This may seem like a dramatic amount of change for one region to experience, but it probably did not seem drastic to the Mesopotamians. Keep in mind the length of time in which these changes occurred, a period of 3,000 years! One division that remained relatively consistent over those 3,000 years was the division between the north and the south. The Mesopotamians saw these two areas as distinct, and even though there were times when both the north and the south were governed by the same institutions, this distinction remained. In the earliest periods of Mesopotamian history, the south is referred to by modern scholars as Sumer. Starting with the Old Babylonian period (of which Hammurabi was the most famous king), the south is called Babylonia, after the famous city of Babylon. The north is usually referred to by modern scholars as Assyria and was named after the ancient city of Ashur, which was one of the main centers of power in the north.

There is more evidence for political history in Mesopotamia than anywhere else in the world at the time. So even though most knowledge of Mesopotamia had been lost until the nineteenth century CE, historians have been able to reconstruct most of Mesopotamian political history because the Mesopotamians kept voluminous amounts of records on clay tablets and stone monuments. However, this reconstruction is still a work in progress. Historians are constantly making alterations to our established understanding of Mesopotamian political history. What follows here is an overview of the most up-to-date understandings of Mesopotamian political history.

—Kevin M. McGeough

The Uruk Period

During the Uruk period (ca. 4000–3100 BCE), named for the southern Mesopotamian city of Uruk (present-day Warka), numerous social, political, and technological advances crucial to later development in the region were introduced. Among these were the appearance of the first cities and early states, the emergence of writing, the development of the fast wheel for the mass

production of pottery, and the replacement of the stamp seal with the cylinder seal. The events and chronology for the early part of this period are not well known, being reconstructed primarily from survey data and very limited archaeological excavation. Our evidence for the Middle and Late Uruk, however, is supplemented by the earliest known texts, primarily economic records and lists, and by southern Mesopotamian material culture discovered at sites in northern Mesopotamia and Syria, southwestern Iran, and southeastern Anatolia. This latter discovery has prompted recent scholarship on the Uruk expansion, including Guillermo Algaze's contentious theory that a world system, a rudimentary colonial empire controlled by Uruk and other southern Mesopotamian states, was in existence at this time.

In the Early Uruk period, southern Mesopotamia (the alluvial plains) experienced a population increase from the preceding Ubaid period. In the northern plains, around the city of Nippur, settlements were fewer but larger, while in the southern plains, around the city of Uruk, settlements were more numerous yet smaller in size. Uruk itself was an exception, a large site in the southern alluvial plains that grew to become, by the Late Uruk period, the biggest city in southern Mesopotamia. It was constructed around two immense religious complexes: Eanna, the precinct of Uruk's patron goddess Inana, and Kullaba, where the sky god An, the head of the pantheon, was worshiped. These complexes, notable for the size and elaborate decoration of the structures they contained, indicated an ability to draw on a massive and organized labor force.

The late fourth-millennium city of Uruk also yielded clay tablets covered with pictographic writing, described as protocuneiform, and cylinder seals, both tools necessary to the development of increasingly sophisticated economic and administrative systems. The mass-produced pottery from these levels is unremarkable in appearance, notable mainly for the presence of large numbers of beveled rim bowls. These coarse mold-made vessels, which may have been used as ration containers, are found in much of the Near East during the Uruk period and are important indicators of contact with southern Mesopotamia.

The appearance of sites far beyond the alluvial plains showing varying degrees of southern Mesopotamian influence, some indistinguishable from southern Mesopotamian settlements in their administrative technology and everyday objects and others with only a few Uruk-style artifacts, began in the Middle Uruk period and reached a peak in the Late Uruk. This has led Guillermo Algaze to infer the existence of a system of southern Mesopotamian colonies, enclaves, and outposts at sites such as Nineveh in northern Mesopotamia, Habuba Kabira in Syria, Godin Tepe in Iran, and Hacinebi in Anatolia. Generally located on major trade routes, the extent of southern Mesopotamian infiltration at these sites seems at least partially dependent on their population densities: sparsely populated regions drew a greater southern Mesopotamian presence than those that were densely populated. While the nature of the interaction between the local inhabitants of these regions and the southern Mesopotamian settlers remains an open question, with Gil Stein identifying a mutually beneficial system of long-distance trade rather than Algaze's informal southern Mesopotamian empire, it is clear that this interaction broke down quite suddenly around 3100 at the end of the Uruk phase. The succeeding Jemdet Nasr period (ca. 3100–2900) saw the further development of the technical innovations of the Uruk period.

THE WARKA VASE

The alabaster Warka vase, standing over three feet (1 meter) tall and carved with five bands of decoration, was recovered from the late-fourth-millennium city of Uruk. Its decorative theme, representing the hierarchy of nature, ascends from a band of water at the bottom to a line of plants, continuing to a row of animals and then to one of nude men bearing offerings. The damaged uppermost band likely depicted a nude servant, with the king standing behind him, presenting an offering to a woman standing in front of two reed bundles, the symbol of Inana, and additional offerings. The woman may be Inana herself or her priestess.

—Karen Sonik

The Political History of the Early Dynastic Period

The Early Dynastic (ED) period in southern Mesopotamia, beginning after the collapse of the Late Uruk period expansion (ca. 2900 BCE) and ending with the rise of the Akkadian empire under Sargon of Akkad (ca. 2334 BCE), saw numerous political developments over its nearly seven-century span. While the division of this period into three phases is based on the archaeological sequence from the Diyala region, each phase roughly corresponds to a different form of political authority. Thus, ED I (ca. 2900–2700) was dominated by assemblies of citizens or tribal elders, ED II (ca. 2700–2600) saw the emergence of wartime kings and the building of city walls, and ED III (ca. 2600–2334) witnessed the rise of kings with dynastic ambitions.

The political configurations of southern Mesopotamia (the alluvial plains) were not uniform, being structured quite differently in the southern plains, the region later known as Sumer, than in the northern plains, the region later known as Akkad. The landscape of the southern plains in ED I was dominated by about 30 city-states, large cities with surrounding villages and farmland. Each city-state was envisioned as belonging to a unique patron god and as having divinely apportioned and thus permanent borders.

STANDARD OF UR

The Standard of Ur, recovered from the Royal Cemetery of Ur, southern Iraq, about 2600–2400 BCE. (The Trustees of The British Museum/Art Resource, NY)

Recovered from Tomb 779 of the ED III period Royal Cemetery of Ur, the so-called Royal Standard of Ur was originally a wooden box of unknown function tapering from base to top. Each of its two long panels and two short ends were decorated with three registers of figural and geometric motifs formed from lapis lazuli, red limestone, and shell set in glue-like bitumen. One of the long sides depicts battle and postbattle scenes, while the other long side depicts a peaceful banquet and processions of men and animals. The king, shown as larger in size than all the other figures, appears on both the war and peace panels.

—Spencer L. Allen

As Nippur had Enlil, the chief god of the Sumerian pantheon, as its patron, it gained special prominence and often served as the arbitrator of intercity conflicts.

The ruler of an ED I city-state was known as *lugal* (great man) or *ensi* (governor) and was responsible for the well-being of the city, serving also as the high priest of the city's patron deity. It is possible that the ruler's political power was granted only at times of crisis by an assembly of citizens, as suggested in legends such as Gilgamesh and Agga. Eventually, however, as the Sumerian city-states began warring regularly among themselves over land and water, both a

full-time king and strong city-walls, two defining characteristics of ED II, became necessary.

Meanwhile, the northern alluvial plains were developing along quite different lines, being structured as a single territorial state usually centered in the city of Kish, although power relocated on occasion. The economy of the northern plains was more secular than in the south. The northern king, known as *en* (lord), was a more secular figure than his southern counterparts, obtaining authority from the city oligarchy rather than from a patron deity.

In time, Kish's influence threatened the south, hastening the collapse of the individual Sumerian city-state. Even when Kish's threat had receded, the city-states fought among themselves for local hegemony. By ED III, kings with dynastic ambitions, claiming divine election and controlling standing armies, replaced the wartime kings of ED II. A conflict between the cities of Umma and Lagash spanning three generations, arbitrated by King Mesalim of Kish (ca. 2500), is typical of the Sumerian rivalries and border disputes that characterized this period.

The reign of King Lugal-zagesi of Uruk marks the end of the Sumerian city-state ideology that characterized the ED III period: Lugal-zagesi extended his rule to include the cities of Ur, Lagash, and Nippur, providing a political model for the succeeding Akkadian empire. Sargon of Akkad, the cupbearer and usurper of King Ur-Zababa of Kish, defeated Lugal-zagesi and unified the northern (Akkad) and southern (Sumer) floodplain under his rule, ending the ED III period.

Councils of Elders in Mesopotamian Towns

In general, a Mesopotamian king's influence on the life of the individual depended on the strength of the monarch and his authority. Strong kings could make demands upon their subjects' resources and labors through taxation, military service, the appropriation of land, and the resettlement of people, whereas weak kings might make little impact on life. Although political, economic, and military matters were controlled by the king and his officials, many aspects of civil life were governed by local bodies. In the countryside and particularly in the less urbanized north, villages governed themselves through village councils, under a local headman. Towns were governed by assemblies (Sumerian *unken*, Akkadian *pubrum*) probably composed of all free adult males, although some legal documents suggest that women might also have been included at times. Some matters were dealt with by an inner council of leading citizens or elders (*sbibutum*). Cities, being larger, were divided into wards (*babtum*), each with their own assembly or council. These could issue warnings and convene hearings on local matters such as the unsatisfactory condition of buildings or the unacceptable behavior of domestic animals; they monitored the movement of strangers in the neighborhood, checked local morals, and made good losses sustained through robbery if the thief was not apprehended. They also dealt with cases in civil law, such as divorce and inheritance disputes.

Professional associations also administered their own affairs. Many cities had a separate trading quarter (*karum*) where merchants could set up their offices, often outside the city walls and usually legally and administratively independent although sanctioned by the state government. The archives at Kanesh in Anatolia provide a picture of the running of a major Assyrian trading station. Karum Kanesh was the organizational center to which merchants in other Assyrian trading stations were answerable. The "lords and fathers" here passed on orders from a head office in Assur, collected the taxes and duties payable to the local ruler, arbitrated in disputes, and took

other decisions; when appropriate they could convene an assembly of the whole *karum*, where decisions were taken by majority vote. Back home in Assur, although the city-state was under the ultimate authority of the ruler (*waklum*, or "overseer," a post held by a member of one leading family), many decisions were taken by the council of city elders or the larger city assembly.

Within the tribal society of the nomad groups, the organization was kin-based, each tribe (known as a *bitu*, or "house") having a hierarchy under the authority of its tribal sheikh. When tribal groups such as the Amorites, Aramaeans, and Chaldaeans gained control of substantial areas, these were divided into tribal territories where this organization held sway such as Bit Yakin from which came the dynasty of Chaldaean kings of Babylon. Village communities also had stronger kinship ties than city dwellers.

Considerable information on local government comes from the archives at Nuzi, a town in the province of Arrapha, whose king was a vassal of Mitanni. One of his queens resided in Nuzi as his representative, and the town maintained her household out of local taxation. Local government in the town and its hinterland was run by the mayor (*bazannu*) who, along with other officials, resided in the government house (*ekallu*). The center of local administration, this contained archives, storerooms, and offices as well as public reception rooms. The mayor was responsible for ensuring the military security of the town and its surrounding area. The Assyrians eventually sacked the town, and the administrative texts record the mustering, equipping, and provisioning of troops in the town's final days. The bureaucratic records also detail the taxes collected by the town to support the infrastructure and personnel of local government, including the army and the town's temples, and for payment to the king in Arrapha. These included finished goods and agricultural produce as well as labor and military service.

Some centuries earlier, in the northern Babylonian city of Sippar, documents refer to *hazannu* as the official representing a ward of the city, whereas the mayor was known as *rabianum*, an office particularly concerned with legal matters and held for a relatively short period,

perhaps a year. The state administration was involved in public works such as the maintenance of irrigation facilities, but the responsibility was shared by the city authorities: the assembly (known as “the city”) led by its chairman (*gal. ukken.nal*), the rabianum, hazannu, and other officials. Local affairs, such as leasing local property and maintaining law and order, the courts, and sanitation, were also in the purview of the local authorities.

The Rise of Akkad

The rise of the Akkadian empire following the Early Dynastic period in Mesopotamia saw the city-states of the northern (Akkad) and southern (Sumer) floodplain united under the centralized rule of a Semitic dynasty based in the capital city of Agade. While its status as the first empire in history is no longer secure, given recent scholarship indicating the complexity of earlier polities in the Near East, the Akkadian empire and its kings achieved a legendary and heroic status unmatched by their successors. It remained a model for future empires and rulers into the Neo-Assyrian period.

Bronze head of Sargon the Great, founder of the First Dynasty of Akkad in southern Mesopotamia. (Time Life Pictures/Getty Images)

Sargon the Great (ca. 2340–2284), the traditional founder of the Akkadian empire, was responsible both for conquering Akkad and Sumer, the latter likely toward the end of his reign, and for military campaigns against Mari, Ebla, northern Mesopotamia, and more far-flung regions in western Iran and southern Anatolia. The extent to which he succeeded in actually integrating these territories into his empire, however, remains uncertain. Sargon also undertook a number of measures to consolidate the territory under his control, destroying defensive city walls in captured cities, replacing the rulers of the powerful southern city-states with Akkadian governors or trustworthy locals, and appointing his daughter, Enheduana, as the high priestess of Nanna at Ur.

The process of expansion and consolidation continued under Sargon's two sons, Rimush (ca. 2284–2275) and Manishtushu (ca. 2275–2260), through campaigns against southeastern Iran and the Arabian coast; the appointment of royal family members to important posts; the redistribution of land, especially from the restive south, to Akkadian elites and military personnel; and the quelling of the rebellions of conquered territories. During the reign of Naram-Sin (ca. 2260–2223), the empire flourished to its greatest extent as the energetic king conducted campaigns in Iran, Magan, and Syria. In an attempt to further secure and legitimate his control over this vast territory, which was still plagued by frequent revolts, Naram-Sin undertook the standardization of imperial accounting and administrative procedures; established the Semitic Akkadian, rather than the agglutinative Sumerian, as the language of imperial administration; set garrisons on the borders of the empire; and took the unprecedented step of proclaiming his own divinity as the god of Agade. This last measure, which had the effect of raising him above the level of any other human king and justifying his dominion over an empire, would later be imitated by kings of other Mesopotamian dynasties.

Although the collapse of Akkad was attributed to the reign of Naram-Sin in the Ur III composition “The Curse of Akkad,” the empire continued to exist into the reign of the last major Sargonic king, Shar-kali-sharri (ca. 2223–2198). The end of his reign, however, was plagued by

revolts against the empire, Gutian raids, and a severe drought that likely affected much of northern Mesopotamia. After his death, a brief interregnum and power struggle was followed by the reign of two more kings, Dudu (ca. 2195–2174) and Shu-durul (ca. 2174–2159), not of the Sargonic line. They ruled little more than the environs of Agade and (possibly) the Diyala Plain, as the Gutians had invaded much of the former imperial territory, and many southern city-states had reasserted their independence.

Akkadian and Ur III Administration

When Sargon, founder of the Akkadian dynasty, conquered the city-states of southern Mesopotamia, he created the first large-scale territorial state in Mesopotamia, an empire whose administration required the development of a more complex bureaucracy than had existed before. Sargon and his successors, particularly Naram-Sin, imposed a cadre of Akkadian provincial governors, known by the traditional title of *ensi*, to administrate the former city-states. Answering to the Crown, the ensis’ authority was backed by military garrisons. These governors visited the capital, Agade, regularly to confer with the king, who also periodically visited the ensis in their provinces. Although temples continued to enjoy considerable power as the seat of the gods from

AKKAD IN THE ARCHAEOLOGICAL RECORD

While a distinctively Akkadian artistic style has been identified and is characterized by a vivid naturalism and subjects such as presentation scenes (in which kings or gods are presented with goods or people), mythological episodes, and battles of the gods, the Akkadian empire is not well represented in the archaeological record. The royal city of Agade remains undiscovered and unexcavated, and few index fossils for the period have been identified at other sites. The general continuity with the material culture of the Sumerian-dominated Early Dynastic period negates the old theory that the Akkadian empire heralded a radical ethnic shift, with the Semitic Akkadians supplanting the established Sumerians and introducing a new model of political organization.

—Karen Sonik

whom monarchs derived their legitimacy, the Akkadian kings took steps to bring them more firmly under their own authority, creating or filling existing temple posts with their own appointees, often members of the royal family. Although the Akkadian kings built and embellished temples, they also seized opportunities to reduce temple estates and the independence of the temples. Nevertheless, there was not a complete break with tradition, the Akkadian kings maintaining the traditional roles and titles derived from control of Kish and Nippur.

Trade, taxation, tribute, and offerings provided substantial resources, but these were swelled by the booty derived from war. Defeated cities yielded not only material booty but also prisoners, who could be employed in public works, and land confiscated from defeated cities and their authorities, which was granted to loyal servants of the crown. Ensis were given estates to support them, located in provinces other than the one they governed in order to prevent the buildup of localized power. Military colonists were settled on expropriated land and contributed to the maintenance of Akkadian authority.

The collapse of the Akkadian empire left a power vacuum out of which the Ur III dynasty eventually emerged as the major power. The Ur III kings elaborated the administrative legacy of

UR AND AKKADIAN EMPIRES

their Akkadian precursors. Ur-Nammu and Shulgi created a bureaucracy of stifling efficiency, with a huge civil service obsessively recording the minutiae of taxes, tribute, and yields from state lands. In principle they upheld traditional Sumerian political organization, dividing Sumer and Akkad into 20 provinces that coincided largely with the main city-states and were governed by ensi who belonged to the local elite. These ensi also controlled the local temples and their households, a major source of state revenue in agricultural produce and the products of industry. On the other hand, the Ur III kings imitated the Akkadians by appointing a military governor (*shagina*) alongside each ensi, drawn from the royal family or from nonlocal sources loyal to the Crown. The names are known of more than 100 princes and princesses, many holding civil or temple posts. The shaginas had responsibility not only for the armed forces stationed in the provinces but also for state dependents settled

on Crown land and were independent of the ensi. From the time of Shulgi onward, the Ur III state maintained a standing army.

Although the Sumerian city-states resented their loss of independence, the Ur III kings created an ideology that helped win them support throughout Babylonia, claiming descent from Uruk's king Gilgamesh. They made much of their piety and role as divinely appointed protectors of the people and promoters of their well-being. They also followed tradition in adopting the system through which temples, and in particular the temple of Enlil in Nippur, were supported by offerings (*bala*) paid on a rotating basis by the individual provinces. Although in principle destined to support the temple, these amounted to taxes. Huge state-run industrial complexes, particularly for making textiles, also contributed to the empire's economic prosperity.

Beyond the core of Sumer and Akkad there was no need for the Ur III kings to subscribe to

traditional ideology; these regions, to the east and north, were ruled by military governors who were granted Crown lands. They were liable for service and paid a tax (*gun mada*) from their produce; settlers on Crown land had paid the same tax under the Akkadians.

Despite the Ur III state's economic efficiency and centralized bureaucratic control and the reverence felt for its kings, it eventually fell apart.

The Ur III Period

The period immediately following the collapse of the Akkadian empire, which saw the reappearance of autonomous city-states and the entrenchment of the Gutians in the northern floodplain and Diyala region, ended with the emergence of a new and highly centralized state. Ruled by the Third Dynasty of Ur (ca. 2112–2004), its vast territorial extent and complex administrative system have led to its frequent characterization as an empire. Despite reverting to Sumerian as the language of bureaucracy, the Ur III state continued several practices introduced under the Akkadian empire, including the deification of its kings during their lifetimes and the appointment of royal family members as high priests and priestesses of the gods.

Ur-Namma (ca. 2112–2095), founder of the Ur III dynasty, was originally the governor of Ur under Utu-hegal, a ruler of Uruk known chiefly for driving the Gutians out of Mesopotamia. Following the death of Utu-hegal, likely Ur-Namma's father or brother, Ur-Namma established himself as king in Ur and gradually gained hegemony over enough of the northern and southern flood-

King Ur-Nammu makes an offering to the moon god Nanna. Ur-Nammu reigned over the Sumerian city of Ur from about 2112–2095 BCE. The stele dates to around 2060 BCE. (Bettmann/Corbis)

plain to take the title of king of Sumer and Akkad. Prior to his death in battle, he built numerous temples and canals; began construction of ziggurats at Ur, Uruk, Eridu, and Nippur; and appointed a daughter as high priestess of Nanna at Ur and a son as high priest of Inana at Uruk. His successor, Shulgi (ca. 2094–2047), continued his father's building program and guided the Ur III state to its zenith, expanding it to the north and east and consolidating it through a series of sweeping administrative and ideological reforms.

The loosely held territories amassed by Ur-Namma were transformed into provinces of a unified state, with each province overseen by a civilian governor, typically of local origin, and a military commander, often a relation of the royal family. The *bala* taxation system, applied to the core provinces of the state, fostered regional interdependence through the collection of specific goods from each province in central depots for redistribution to the other provinces. Shulgi also created a standing army, introduced standard accounting practices and a new calendrical system, wrote the first Mesopotamian law collection, and established scribal schools to train bureaucrats in Sumerian, likely a dead language at this time, and in literary compositions

THE UR III ZIGGURATS

The practice of placing temples on platforms to lift them closer to the heavens, dating back to the Ubaid period in Mesopotamia, was adapted during the reign of Ur-Namma to form the ziggurat, a series of stepped rectangular platforms with a temple set at the very top. The final form, resembling a mountain, comprised a solid core of sun-dried mud brick with a more durable baked brick lining its exterior surfaces. Whether these structures served a purpose beyond the elevation of the temple is unknown, although Herodotus wrote that the Sacred Marriage Ceremony, part of the New Year Festival, took place atop them.

—Karen Sonik

that promoted the king as the central force in the state. His self-deification, imitated by his successors, furthered his political agenda: declaring himself a “god of the land,” Shulgi simultaneously avoided association with any single city-state and claimed the support of his divine family, the gods themselves, for his rule.

Shulgi’s successors, sons Amar-Sin (ca. 2046–2038) and Shu-Sin (ca. 2037–2027), managed to hold most of the territory he had conquered, although the Amorite raids early in Shu-Sin’s reign signaled a growing political instability. Under Ibbi-Sin (ca. 2026–2004), son of Shu-Sin, increased pressure by the Amorites and the revolt of one city-state after another led to the rapid disintegration of the Ur III state. Soon only Ur and its environs were left, and even these were lost when the Elamites sacked the city in circa 2004, taking Ibbi-Sin prisoner and bringing the Ur III period to a close.

The Isin-Larsa Period

The Ur III empire broke up into a number of autonomous smaller states, controlling and fighting over other ancient cities. Initially the most important was Isin, whose lands stretched from Mashkan Shapir and Kazallu in the north to Uruk, Eridu, and other southern cities. These included, crucially, Nippur, which gave Isin nominal legitimacy as the successor of Ur III, theoretically appointed by the gods as the ruling state of Sumer. Ishbi-Erra of Isin regained control of Ur and eventually defeated the Elamites, avenging Ur’s fall. He restored many of the buildings of Ur and other cities and deliberately followed many of the practices and norms of the Ur III empire. A number of kings in this period have left law codes, following the earlier example of Shulgi and consciously upholding and imitating ancient values. Sumerian continued to be the language of scholarship but was no longer spoken; Akkadian, in contrast, was used for international communication from Anatolia to Elam.

But times were changing. Whereas king and temple had generally controlled the state economically in earlier times, private enterprise now began to flourish, the government receiving taxes from the success of privately financed ventures rather than the profits of publicly controlled enterprises. The temple authorities, while still of great importance, now gave way politically to the king, who had full control of the state’s administration, as is vividly shown in a number of surviving archives. Frequent records of the construction or restoration of city walls reflect the instability of the times and the need for constant defense. No ruler was strong enough to control all of southern Mesopotamia.

Many of the independent kingdoms, here and farther west, had rulers with Amorite names, now clearly integrated into Mesopotamian society, while in northern Mesopotamia many of the dynasties were Hurrian. These successor states included Susa, Assur, Eshnunna, Yamhad, and,

most significantly, Larsa, which by the reign of Lipit-Ishtar of Isin had thrown off Isin's authority and was challenging Isin's primacy.

Gungunum of Larsa claimed descent from earlier kings of the city, but his forebears were in reality Amorite sheikhs. He and his father had probably been governors of Isin's province of Lagash, which included Larsa. Under Gungunum, Larsa probably came to control Nippur, Susa, and perhaps Uruk and in 1925 seized Ur from Isin, thereby gaining control of the still lucrative Gulf trade, especially in copper, now conducted through the trading entrepôt of Dilmun. Political changes did not affect other traditional aspects of life. For example, Ibbi-Sin's daughter remained entu-priestess of Nanna at Ur until her death, when she was replaced by Ishbi-Erra's daughter; similarly, the Isin incumbent continued in office when Larsa took Ur.

For several centuries, political power was very volatile. States expanded and contracted, and from time to time new ones gained a foothold. Uruk briefly controlled Nippur and under Sinkashid (an Amorite) for a while held the balance of power between Isin and Larsa through its control of the middle Euphrates. In 1834 BCE, Kudur-Mabuk, Amorite ruler of Emutbal on the eastern flank of Mesopotamia, gained control of Larsa, giving the throne to his son Warad-Sin, who reigned until 1823 when he was succeeded by his brother, Rim-Sin I. Their sister became entu-priestess in Ur. The family embarked on an ambitious restoration program in the southern cities, including Ur and Nippur. Rim-Sin defeated Uruk, Isin, Rapiqum, and Babylon, along with Sutu nomads from the west, in 1804, and conquered Isin in 1794, a triumph that he celebrated in his annual year-names throughout the remaining 31 years of his reign; he was to dominate the south until 1763.

Elam, freed of Sumerian domination, was entering a period of expansion and affluence. Its control of a major source of the important and scarce metal, tin, must have played a substantial part in its prosperity and power. Until defeated by Hammurabi in the eighteenth century BCE it was a major player in Mesopotamian politics, closely involved with the states on its borders, particularly Eshnunna, which enjoyed considerable power through its control of trade routes

➤ OLD BABYLONIAN LETTERS

Letters exchanged between Ibbi-Sin, the last Ur III king, and the governor of Isin, Ishbi-Erra, survived as Old Babylonian school texts. Many thousands of letters have been found in palaces and other archives dealing with official matters such as international relations or diplomatic gifts or business concerns such as prices and commodities but also events such as the capture of a lion. The extensive Assyrian palace archives at Nineveh included letters on a wide range of subjects such as omens, military and diplomatic matters, and domestic concerns. Some of the most interesting are personal letters, preserved, for example, in the palaces at Mari and Karana and in the Old Assyrian trading station of Kanesh. They show individuals worrying about their health and personal relationships, sending each other gifts, or complaining about poor-quality slaves. Queen Iltani of Karana received a letter from her sister in Assur reporting her failure to obtain a lapis lazuli necklace that Iltani desired; another sister wrote asking for new slaves and sent some wool and a container of shrimp as a sweetener with her request. Zimri-Lim of Mari and his wife Shibtu exchanged many letters while he was absent about business matters and private concerns, from the birth of twins to Shibtu's request that Zimri-Lim wear the coat and tunic she had made him. An earlier Mari ruler, the ne'er-do-well Yasmah-Addu, received many admonitory letters from his father Shamshi-Adad; those from his "perfect" brother, Ishme-Dagan, were scarcely more conciliatory.

—Jane R. McIntosh

into the Iranian plateau. Competing for power with Der and Kish, Eshnunna's territories fluctuated in extent. It expanded in the later nineteenth century BCE under Ipiq-Adad II, coming into conflict with neighboring Babylon, Assur, and Larsa. Under his successor, Eshnunna gained control of the middle regions as far east as Mari and as far north as the source of the Khabor, conquering Assur, capital of the small city-state of Assur (Assyria).

Hittite Political History in the Second Millennium

Hittite hegemony waxed and waned twice in Anatolia between 1650 and 1200 BCE, with the Hittites establishing themselves as a major force in the ancient Near East with their second rise to power. Records of the Hittites, who spoke the earliest written Indo-European language, first appear during the reign of Hattushili I (ca. 1650–1620) in his capital city of Hattusha (present-day Bogazkoy). Hattushili's Testament refers to a previous king and queen, Labarna and Tawananna, indicating that political and social institutions were already in place by Hattushili's reign. The reconstruction of any more detailed events of the preceding 200 years, however, is mostly reliant on the archaeological record.

The history of second-millennium Anatolia begins with the Old Assyrian trading colonies established in Kanesh (present-day Kültepe) by Assyrian merchants. They traded Babylonian textiles and Iranian tin in exchange for Anatolia's

abundant copper, which was a key ingredient of bronze alloy. At the peak, prior to their destruction in 1830 BCE, the Kanesh colonies were populated by about 500 Assyrians. The years between this destruction and the appearance of Hattushili in the mid-seventeenth century BCE were probably characterized by competition and warfare between independent Anatolian city-states. This somewhat chaotic period was brought to an end by Labarna, a ruler from Kussara, who established a power base in the refortified ruins of the city of Hattusha and took control of the other regional cities.

Hattushili I's reign, as well as that of his grandson and successor Murshili I, was spent establishing and maintaining control over neighboring cities. Hattushili conducted six military campaigns during his reign. The first was to the area north of his capital, but with his second campaign he extended Hittite power into northern Syria. This latter campaign prompted an attack by the then-powerful Hurrians in eastern Anatolia, precipitating revolts by all of the regions that Hattushili had previously conquered. Reduced to ruling the areas only immediately surrounding Hattusha, Hattushili appealed to the Hittite sun goddess Arinna and spent his next three campaigns successfully reasserting and extending his control in Anatolia and northern Syria. Indeed, his military conquests were so substantial that he likened himself to Mesopotamia's first true empire builder, Sargon of Akkad (ca. twenty-fourth century BCE).

After Hattushili's death, Murshili I (ca. 1620–1590 BCE) capably consolidated the lands conquered by his grandfather. Under Murshili's leadership, the Hittite kingdom became powerful enough to soundly destroy the city of Alalakh and defeat the kingdom of Yamhad, which was based in Aleppo and had been the dominant power in the region. Murshili then turned his attention to the east in a successful campaign against the great city of Babylon. He did not follow up on this victory but instead returned to Hattusha after sacking the city and leaving behind a power vacuum in Babylon that was ultimately filled by the Kassites, who would maintain their dynasty for nearly 400 years.

The territorial gains and consolidation achieved by Hattushili and Murshili were ulti-

Lions flank the entrance to the Great Fortress at Hattusha in present-day Turkey. Hattusha was the capital and greatest city of the Hittite empire during the second millennium BCE. (Shutterstock)

mately futile because in 1590 Murshili was assassinated by his brother-in-law Hantili. Many years later, Hantili was in turn assassinated by his co-conspirator Zidanta. The first Hittite Golden Age, as described by Telipinu a century later, thus ended with Murshili's death.

In the interim between Murshili's death and the reign of Telipinu (ca. 1525–1500), no dynasty was able to successfully establish itself: one coup d'état followed on the heels of another. Attempting to terminate this vicious cycle, Telipinu defined the order of succession for the Hittite throne in his edict of the late 16th century. He also stressed the importance of clemency—banishing rather than executing—those he deemed guilty of the most recent attempted coup. Unfortunately, Telipinu died without a surviving male heir, and the calm he had inspired during his reign was followed by another half century of political instability.

The 50 years following the death of Telipinu, which marked the close of the Old Hittite Kingdom, is sometimes referred to as the Middle Kingdom. Since so little is known about the period and since the kings of this age do not seem to have accomplished too many deeds of note, scholars have increasingly abandoned this term. The New Kingdom, however, commenced with a distinct bang during the reign of Tudhaliya II (ca. 1450–1420). Despite an Egyptian-Mitanni alliance that initially swayed Aleppo's alliance from Hattusha, Tudhaliya ultimately defeated both Aleppo and Mitanni. The attempt of his successor, Arnuwanda I (ca. 1420–1400), to extend the Hittite sphere of influence to the west led to trouble, however, as the Aegean power Ahhijawa led a revolt to take control of Arzawa, the western half of Anatolia. The stability of the New Hittite Kingdom was further threatened by the encroachment into the Hattusha region of the Kaska, a northern Anatolian people. Rebellion erupted throughout the kingdom, and the capital city was apparently destroyed during the reign of Tudhaliya III (ca. 1400–1380). All rivals now considered the Hittite power dead.

Following the ruin of these rebellions, Tudhaliya III's son Shuppiluliuma I, after an early defeat by Mitanni, eventually proved himself as a great general. Tudhaliya III was killed in a coup by senior military officials who then placed

➤ THE EDICT OF TELIPINU

With his late-sixteenth-century edict, Telipinu set out to reestablish the structure of the Hittite state by strictly defining the order of royal succession and ending the series of coups that had endangered the kingdom. The king was to become accountable to the gods and the *panku*, an ad hoc assembly of nobles and administrators, and even to be held liable for murdering a member of the royal family. In return, the *panku* protected the king from attempted seizures of power. The edict also stated that only an offender was to be held liable for murder. Innocent family members could no longer be executed for the offender's crime, a striking reversal of Mesopotamian legal tradition.

—Spencer L. Allen

Shuppiluliuma I on the throne (ca. 1370–1330). The first half of Shuppiluliuma's 40-year reign was focused on reclaiming Anatolia for the Hittites, forcing the submission of the Kaska, Azzi, and Arzawa. In his second Syrian campaign, he reestablished the Hittite Kingdom as an international power. After attacking the Mitannian king Tushratta and eventually driving him away from the Mitanni capital of Washshukanni, Shuppiluliuma installed a Mitannian prince as a Hittite vassal in western Mitanni. Now free to extend the Hittite sphere of influence over Aleppo and Carchemish, where he installed his son as ruler, as well as Alalakh, Nuhashshe, Amurru, and eventually Qadesh, even the pharaoh of Egypt ultimately recognized Shuppiluliuma's power, referring to him as an equal. Indeed, after Tutankhamen's death, the pharaoh's widow requested one of Shuppiluliuma's sons as her new husband. This son, however, was murdered in Egypt, so the dynastic alliance between Egypt and the emerging Hittite empire never materialized. Shuppiluliuma did, however, form a dynastic alliance in Mesopotamia by marrying a Babylonian princess late in his reign.

The end of Shuppiluliuma's reign was marred by a plague, which lasted 20 years. Brought to Anatolia by prisoners of war, the plague ended the reigns of both Shuppiluliuma and his eldest son Arnuwanda II, leaving the younger son

Murshili II (ca. 1339–1306) to ascend the throne and pray for relief from the plague. With the gods' help, the plague subsided. With the help of his brother, who acted as king in Carchemish and kept northern Syria under control, Murshili II was able to consolidate the territories conquered by his predecessor and to force the submission of the Kaska, Arzawa, and Azzi in Anatolia. Threats from the Assyrians and Egyptians then forced Murshili II to focus his attention on Syria. The power vacuum left by the fall of the Mitannian empire at this time provided the opportunity for the upcoming Assyrian armies to move west into Carchemish. Murshili II quickly reclaimed Carchemish but near the end of his reign had to face an attempt by the Nineteenth Dynasty of Egypt to reestablish its international empire to Qadesh and Amurru in Syria.

The real threat came when Ramses II ascended the throne during the reign of Murshili II's successor, Muwatalli II (ca. 1306–1282). In an effort to maintain Hittite control in Syria, Muwatalli II moved his capital to Tarkhuntassha, nearer the Taurus Mountains. In Ramses's fifth year, the two armies met at the famous Battle of Qadesh in northern Syria. The result was a draw, but the Egyptians withdrew from the region. Years later, Muwatalli II's brother Hattushili III (ca. 1275–1245) and Ramses ratified a parity treaty, later sealed by dynastic marriage. The governor of northern Anatolia, Hattushili III, exiled and usurped power from Muwatalli's son Urhi-Teshub/Murshili III (ca. 1282–1275) and moved the capital back to Hattusha, installing Murshili III's brother Karunta as vassal. Meanwhile, the Assyrians continued their western campaign by seizing Mitanni from Hittite control, first making it a province and then annexing it into the empire. Hattushili turned to Babylon for help, but the alliance was brief. Assyria had become too powerful an international power, prompting Hattushili's peace agreement with Ramses of Egypt in order to concentrate on Assyria.

The reigns of Tudhaliya IV (ca. 1250–1220) and Shuppiluliuma II (ca. 1215–1200) signaled the end of the empire, as the Hittites suffered continued diplomatic and military defeats. Karunta momentarily captured Hattusha from his cousin, while Assyria, Ahhijawa, and the Kaska

remained external threats. An Egyptian letter from the reign of Ramses III claims that Hattusha along with all the eastern Levant was defeated by the so-called Sea Peoples, although no sign of a corresponding foreign attack has been uncovered. The city had been abandoned, but the true identity of the invading peoples is unknown.

The Cultures of Anatolia, 4000–1000 BCE

The Anatolian Peninsula and its geographical environs were home to numerous ethnic and linguistic groups between 4000 and 1000 BCE. These three millennia can be divided into four periods: the Late Chalcolithic period (ca. 4000–3000), the Early Bronze Age (EBA, ca. 3000–2500), the Middle Bronze Age (MBA, ca. 2500–2000), and the Late Bronze Age (LBA, ca. 2000–1200).

The peoples of Anatolia, many of whom were part of the Transcaucasian culture, were already in the fourth millennium practicing intensive farming and animal husbandry as well as exploiting their natural resources, which suggests that these settlements were already organized by tribal leaders. The pottery of this period in eastern Anatolia was handmade, often with burnished black exteriors and red interiors. Similar pottery from southwestern Europe suggests that a Balkano-Anatolian culture existed in northern Anatolia and the Black Sea region. The most significant achievement of the Chalcolithic period in Anatolia was the discovery of copper's ductility and the creation of copper alloys, particularly bronze, for use in making both weapons and ornamental items. Indeed, metallurgy was first developed in the highlands of Anatolia and spread into Syria and Mesopotamia.

Only toward the end of the fourth millennium did the Uruk cultural expansion, originating in southern Mesopotamia, influence the otherwise indigenous development of the late Chalcolithic Anatolian settlements. While the extent of the political and economic affiliation of Anatolia, especially the Amuq Plain, Anti-Taurus regions, and southeastern Anatolia, with Uruk is debated, Anatolia was likely technically independent at this time. Nonetheless, it was greatly influenced by the cultural, commercial, and political reality of northern Syria and Mesopotamia, which appear to have had enormous range at this time. Certainly, with the collapse of the Uruk expansion around 2900 BCE, the number of urban centers in Anatolia clearly decreased. Furthermore, the urban settlements in southeastern Anatolia regressed during the early EBA, more closely resembling central Anatolia both in its agricultural practices and its architecture. In

the region of Thrace to the west, the city of Troy first appeared as a fortified settlement around 3000 BCE and quickly grew into a state-level complex society as a regional economic and administrative center. Troy's expansion into a political and industrial center over the course of the third millennium is similar to—though independent of—the societal restructuring that occurred in the eastern half of Anatolia in the third millennium.

Defined by the surrounding geography and probably ruled by tribal leaders, most settlements in the early third millennium were mixed-farming villages. While the size and population of most Anatolian EBA sites are difficult to assess because they have been only partially excavated, archaeologists can still identify basic economic activities, organization, and population development. Over the course of the EBA, the settlements producing the best goods became

economic centers, developing into industrial town-sized hubs that would eventually become regional polities. A change reflective of the increase in population rather than of a cultural shift was the switch from the cultivation of emmer and einkorn wheat to bread wheat and barley, which were easier to process after harvest. This agricultural development, along with the large-scale introduction of olive, grape, and fig cultivation, occurred during the EBA. The nomadic peoples also saw a shift in their livelihood as the increase in population and the practice of cultivating any geographical topology pushed them into the mountains. This was especially true in the Black Sea region.

Already home to many indigenous populations, Anatolia, a natural bridge between Asia and Europe, became home to many migratory peoples in the third millennium. Unfortunately, due to the homogeneity of the archaeological evidence, the pottery, and the architecture and the absence of textual documents, it is difficult to determine the identity of a given settlement in Anatolia. Because each invading newly arriving people soon assimilated to the culture of the preexisting inhabitants, a new ethnic group's arrival can only be determined by the disruption in the material culture of the archaeological record.

In the MBA, the number of urban centers declined in Anatolia, again allowing small city-states to incorporate the surrounding towns and villages and transform into larger regional capitals. This may have been the result of increased tribal warfare, made possible through advances in metallurgy near the close of the EBA. Because of the isolation of central and eastern Anatolia from Mesopotamian culture in the MBA as well as their ability to quickly acculturate immigrant peoples, the local cultures continued to evolve slowly until the arrival of the Assyrian merchants in the early second millennium.

Linguistically, scholars have found that the various Indo-European-speaking peoples probably arrived in Anatolia during the third millennium. An analysis of these languages, Neshite or Hittite, Luwian, and Palaic, from the second and first millennia texts indicates that these languages are so closely related that the peoples who spoke them likely arrived in Anatolia as

Relief sculpture, from around 1200 BCE, depicting figures armed with sickle-like objects, at the Hittite site of Yazilikaya, in central Anatolia, Turkey. (Adam Woolfitt/Corbis)

part of small continuous waves of migrations, not as independent groups at different times. Old Hittite Law (ca. 1600) notes that Pala, Luwiyā, and Hattusha, the Hittite capital, were also names of provinces in the Hittite Kingdom. The specific origins of these peoples and how large a portion of the Anatolian population they constituted in the third and second millennia are, however, uncertain. Other groups living in Anatolia at this time include the Hattians, an indigenous people of central Anatolia, and the Hurrians, a group linguistically related to the Urartians of the first millennium. The language of the Hattians survived largely because their gods, festivals, and myth were incorporated into Hittite ritual texts found in the Hattusha archives and because other Hattian words were retained as names of native Anatolian flora and fauna. Knowl-

edge of the Hurrians remains obscure prior to the eighteenth century due to a lack of relevant architectural and textual remains, but their probable origin is the Caucasus region. Their ethnocultural influence in Anatolia is difficult to determine.

Near the beginning of the LBA, merchants from Assyria settled in trading colonies, or *karum*, near the city of Kanesh, introducing Anatolia to cuneiform, the wedge-shaped writing system of Sumer, although cuneiform did not take hold at this time. The earliest Hittite texts date to the late seventeenth century, to the reign of the first historical Hittite king Hattushili I, and are written in a Babylonian script. Hattushili's capital Hattusha was located in central Anatolia, which had grown from a small site in the EBA to prosperity in the nineteenth and eighteenth centuries.

Despite Hittite hegemony during much of the second millennium, many Hittites lived in rural settlements. Like most Anatolians, the Hittites were agriculturalists who also raised livestock and were noted for their beekeeping. An Indo-European-speaking group who referred to their language as Neshite, or "from Kanesh," the Hittite heritage was likely a mix of Indo-European and Hattic peoples. This dual heritage is reflected in the institutions of both kingship and queenship, which were inherited separately, as well as in ritual and mythology. While alive, the king was the gods' regent, judge, and high priest, but he "became a god" at death.

Although Hurrian was first recognized in a tablet from the El-Amarna archives in Egypt, most Hurrian texts have been uncovered at Hattusha. The Hurrians probably settled in Anatolia in the middle of the third millennium and, later, in the Khabor River valley. The presence of Hurrian gods in the twenty-fourth-century Eblaite pantheon supports this early date. Hurrian migration into the Euphrates, Tigris, and Orontes valleys sped up after King Shamshi-Adad I of Assyria's death in the eighteenth century. Within two centuries, they would become one of the largest ethnic groups in southeastern and eastern Anatolia, despite Hittite military campaigns against them during the reigns of Hattushili I and Murshili I. Of obscure beginnings and unknown state organization, the Mitannian King-

➤ HITTITES AND THE BIBLE

English usage recognizes four types of Hittites. Properly, the Hittites are second-millennium speakers of the Indo-European languages of Neshite and Luwian. However, the term can also refer to their geographical predecessors, the indigenous Hattians whose memory is preserved in Hittite texts from Hattusha. In the Bible (Gen. 23), Abraham encounters near Hebron several biblical Hittites, sons of Heth. Although likely contemporaries of Abraham, there is no indication that Hattians, Neshites, or Luwians traveled into southern Palestine at that time. Notably, biblical Hittites are also mentioned as inhabitants of Canaan in the historical books, as in 1 Kings 9:20. A final group, identified as the Neo-Hittites by scholars, likely spoke a Northwest Semitic language rather than an Indo-European one.

—Spencer L. Allen

dom rose to power in the second half of the sixteenth century, and its influence continued through the fourteenth century, as indicated by a dynastic marriage with the Egyptian pharaoh Amenhotep III (ca. 1388–1350). By that century, they compromised the majority population in the kingdom of Arrapha and the city of Nuzi in eastern Mesopotamia, and they also exerted a significant but not majority force as far west as Alalakh of Yamhad, Emar, Ugarit, and even Kiz-zuwadna. Interestingly, Mitanni's ruling elite have personal names betraying an Indo-Aryan affiliation, as do various of their technical words. After its defeats by the Hittite king Shuppiluliuma I in the late fourteenth century, Mitanni became a Hittite vassal until the thirteenth century, when the Assyrian king Shalmaneser I conquered the area. Once incorporated into the Assyrian state, the Hurrian populations assimilated and began speaking Akkadian.

A few other peoples should be mentioned briefly. The Palaicans of north-central Anatolia are another Indo-European-speaking people whose memory survives in a few religious texts. Like Hittite, the Palaic language and religious thought were influenced by Hattic. Displaced by the Kaska, a nomadic people near the Black Sea, the Palaic language is the first known Indo-European

language to have gone extinct. The arrival of the Kaska in the seventeenth century disrupted the continuity between the Black Sea and central Anatolia. Although they were only organized at the tribal level, they continued to fight with the Hittites during the second millennium, sacking Hattusha more than once. Finally, the Luwian-language family was spoken in southern and southwestern Anatolia and was likely spoken by the Trojans. Luwian is first attested in cuneiform from the sixteenth- to the fourteenth-century archives in Hattusha, but a native hieroglyphic writing system called Neo-Hittite is attested from the fourteenth to the seventh centuries, and an

alphabetic system existed in the fifth to third centuries BCE.

■ Introduction: Political Entities in Ancient China

The origins of the modern Chinese state can be found in this period. Although the region that we now think of as China had been inhabited for thousands of years prior to this, the first unified Chinese state appears during the time under consideration here. Like the ancient Egyptians, ancient Chinese historians saw Chinese history as a series of successive dynasties. Toward 1000 BCE, these historians came to understand that these dynasties ruled according to what they referred to as a "Mandate from Heaven." This mandate implied that the right to rule was granted by the gods and was based on moral principles. Thus, a ruling family, if not acting in accordance with moral values, could be removed from power. Based on this conception of successive dynasties and a cycle in which a ruling family starts out moral, eventually acts immorally, and is replaced by a new ruling family, Chinese historians understood their own political history as inherently linear and cyclical. To a certain extent, this conception of Chinese history is still invoked by historians today, although the moral dimension is often abandoned in favor of other historical explanations. These ancient histories are useful for scholars in the reconstruction of ancient China, although these sources must be used cautiously).

The cyclical conception of successive dynasties, however, does not seem to accurately re-

flect the situation in China during the Neolithic Age and the Bronze Age. During these periods, there seem to have been numerous separate power centers, operating concurrently. China is very diverse geographically and during the Neolithic was inhabited by numerous cultural groups. According to tradition, from these Neolithic groups three historical dynasties emerged: the Xia, the Shang, and the Western Zhou. While the traditional accounts and chronologies describe these as successive dynasties, in actual fact they may have overlapped with one another. The following entries explore the problems with reconstructing ancient Chinese political history and provide an overview of what is known about the Xia, Shang, and Western Zhou.

China's Mythical Past

China's mythical past is populated by a progression of gods, demigods, and legendary kings stretching from remote antiquity to early historical periods as recorded in traditional accounts of Chinese history. Many ancient myths have come down in fragments, have been lost, or have been altered or transmitted selectively in accordance with varying priorities and worldviews. As a result, much of China's mythical past is inaccessible, appears contradictory from one source to

MAJOR SITES OF THE XIA, SHANG, AND ZHOU DYNASTIES

the next, or came relatively late into the long history of Chinese literature. Nonetheless, China's myths of early times, rulers, and events are important due in part to the fascination with and reverence for China's mythical past.

Categorizing and describing gods, culture heroes, and kings is complex and marked by layers of uncertainty. Some of the gods and kings are also fantastical creatures, including dragons or beings that are part animal or that have the ability to turn into animals. In some accounts, this shape-shifting ability is attributed to the legendary sage rulers of the late third millennium BCE: Yao, Shun, and Yu. Yao and Shun were often portrayed as ideal rulers who chose successors based on merit over their own sons. Yu was awarded rule for his hard work taming the floods. He is

traditionally viewed as the first ruler of China's first dynasty, the Xia (Hsia). In their capacity as sage rulers and moral examples, these legendary figures have been historicized and humanized by Confucian and other scholars who looked to them as virtuous examples for later rulers to emulate. However, other myths and appropriations of these figures emphasized their shamanic abilities and links with the natural world.

Extraordinary powers and divine status are more freely attributed to the still earlier Three Sovereigns who were thought to have advanced Chinese civilization in the early third millennium BCE. Fuxi (Fu-hsi) is the culture hero credited with introducing new weapons for hunting and nets for fishing, domesticating animals, and creating the divination trigrams of the Yijing

This is an image of Pangu, from the *Sancai Tuhui*, a Chinese encyclopedia first published in 1609. In Chinese mythology, Pangu (“Pan” means “Coil up,” “Gu” means “Antiquity”) is the creator of the world, the first divine human who was miraculously born within the cosmos egg. It is he who separates heaven and earth, and when he dies, his body transforms into the universe. (Wang Qi and Wang Erbin, comps. *Sancaituhui*. Jinchang Baohanlou Kanben, 1609. Preserved in the Library of Literature Institute, Chinese Academy of Social Sciences)

(I-Ching). He is often paired with Nu Gua (Nü-kua, Nüwa), the female deity who repairs the cosmos and creates human beings. Both are depicted with human upper bodies and serpent tails. The overlapping categories of deity, culture hero, human, and animal are further illustrated by the other two Sovereigns, Shennong (Shennong) and Huangdi (Huang-ti). Shennong is a nature deity and cultural hero of agriculture whose myths include some animal features and a transparent stomach useful for his advances in discovering plants’ medicinal uses. Huangdi, also known as the “Yellow Emperor,” became synonymous with Chinese civilization through his

associations with writing, silk, medicine, modes of transportation, the calendar, and many other inventions and advances. He remains popular as the ancestor of the Chinese people, a god, and a prototypical Daoist immortal who ascended to heaven on a dragon.

The accumulated myths that transmit China’s mythical past synthesize the past of various regions in, and at times beyond, present-day China. Additionally, these myths partially shape the mythical past of other countries that have been in China’s cultural sphere of influence. The cosmogonic myth of Pangu exemplifies both tendencies. In this creation myth, the birth and growth of Pangu separates heaven from earth, and his death fills both as his breath becomes wind, his blood becomes rivers, and his body yields a variety of new terrestrial and celestial forms. This myth is related to several early creation stories from other cultures including the dismemberment of the Vedic cosmic man, Purusha. That myth provides a rationale for India’s caste system as each of the four main classes emerge hierarchically from the mouth, arms, legs, and feet of Purusha. Similarly, interpretations of the Chinese myth attribute Pangu’s parasites to the origins of the common people. There are other interesting cross-cultural comparisons, such as the later Japanese creation myth where the sun and moon are born from Izanagi’s left and right eyes. For Izanagi, this happened during a purification ritual after witnessing death rather than in death, but the parallel is striking as the sun and moon were born from Pangu’s left and right eyes, respectively, in the Chinese myth. Although intriguing, the similarities are not surprising in this case, as early Japanese histories—including such foundational mythical accounts compiled in the early eighth century CE—were deeply influenced by Chinese models.

The imagery and themes of China’s accounts of a mythical past continuously influenced their own literature as well. While this is particularly explicit in Confucian accounts of sage rulers in an earlier Golden Age, it can be found in Daoist writing and general cosmological assumptions throughout Chinese literature and thought. This same Pangu mythical example of cosmic origins describes the separation of heaven and earth as the differentiation of yang and yin, respectively,

► PROBLEMS ACCESSING CHINA'S MYTHICAL PAST

In his influential essay “Myths of Ancient China,” Derk Bodde describes three key problems responsible for much of the difficulty, complexity, and lack of consensus with regard to these myths. The first concerns euhemerization, a theory that the gods of mythology were derived from extraordinary humans in history. That is, there was an actual human whose exploits and reputation grew over time and attained divine status. Although Chinese religion offers many examples of humans graduating to divine status, Chinese mythology illustrates an inversion of this theory. The mythical gods, culture heroes, and legendary rulers of China appear instead to have been deities originally who were later historicized as human heroes and sage rulers. Certain fantastical and extrahuman elements were stripped out over time rather than added. Remaining incredible characteristics were further removed or rationalized by Confucian scholars who may have viewed some of these elements as implausible embellishments consistent with the original euhemerization theory rather than original remnants disappearing in a reverse euhemerization. Bodde provides the example of a text where Confucius answers a question from a disciple about Huangdi’s 300-year lifespan by asserting that the common mythic age conflated the Yellow Emperor’s 100-year lifespan with the following century of reverence and a further 100 years of following his teachings.

The second set of problems concerns fragmentation and language. Fragments of myths survive in later works. Instead of receiving the full myth from ancient times, we are often left with a puz-

zling reference or several lines from an earlier myth. Bodde points to the circa fourth-century BCE Heavenly Questions in which enigmatic allusions to earlier myths are asked in question form with neither answers nor context provided. Problems from fragmentation are compounded by ambiguity inherent to classical Chinese language. There are multiple interpretive possibilities—due to homophones, similar characters that might be confused with each other, and often no indication of tense, number, or gender—that cannot be narrowed down to one conclusive meaning, as the typically fragmentary account may not provide adequate context.

The third problem addresses chronology. It was during the Han dynasty (206 BCE–220 CE) when past writings were collected, edited, and written about by scholars. Han times, priorities, worldview, and sensibilities were importantly different from early Zhou (Chou) writings and myths, some of which originated a millennium or more before the Han editors wrote, reshaped, or selectively systematized accounts of earlier eras. Aside from earlier archaeological evidence, it is often through these Han compositions and later writings that we have imperfect access to the Zhou and Shang, much less to China’s more ancient mythical past.

—John Harding

Bibliography

from a previously undifferentiated whole, Hundun. Literary passages, such as the story from the third-century BCE Daoist classic *Zhuangzi* (*Chuang-tzu*), play with this idea by personifying chaos as a faceless ruler named Hundun (Hun-tun) who dies through the misguided efforts of his friends to give him the openings (eyes, nostrils, mouth, and ears) that he lacked. While these differentiating features would appear beneficial and fit many notions of progress, the ideal direction in Daoism is a return to the chaotic and undifferentiated whole. The interplay between cosmology and the most distant mythical past in this early Daoist work suggests nature as

a guide for spontaneous action in harmony with larger cosmic patterns and relates cosmogonic origins with the ineffable mysterious Dao beyond distinctions. The mythical past is used rather differently in this Daoist example relative to Confucians lauding paragons of virtue such as the rulers Yao and Shun, but for both the mythical past is more representative of an ideal than is the present or future.

The Xia Dynasty and the City of Erlitou

According to the traditional conception of Chinese history, the Xia dynasty was inaugurated by Yu during the twenty-second century BCE. Seventeen kings led the Xia; the last ruler was Jie, who, according to tradition, allowed his wife to pressure him to rule over China harshly and violently. In response, Tang led a rebellion against him, overthrew him, and founded the Shang dynasty. Modern scholars had long assumed that this was a mythical dynasty, with the stories bearing little or no historicity. Excavations at the site of Erlitou, however, have led many scholars to rethink this position, suggesting that in fact there was a Xia dynasty.

Excavations at Erlitou were the first to identify a material culture tradition that seems to have overlapped with the traditional chronological and geographic range of Xia society. Archaeologists have identified Erlitou cultural features throughout western Henan and southern Shanxi, which is roughly the same region where Xia power was supposedly centered. Chronologically, Erlitou culture is not completely agreed upon, but the rough range of dates running from 2000–1300 BCE lines up well with the expected chronology of the Xia dynasty. More importantly, Erlitou remains are stratigraphically located above Neolithic Longshan remains but beneath Shang remains, precisely where Xia remains would be expected.

The site of Erlitou is the largest Erlitou site so far identified. A large palace, 11,955 square yards

(10,000 square meters) in size, has been excavated. It was built on top of a large rammed earth platform, lifting the palace about 2.6 feet (0.8 meter) above the surrounding parts of the town. The palace has a large main gate, a large open courtyard, and a large hall. Another smaller platform also has a large hall and is associated with a tomb. Some have suggested that this may have been the location of ancestor veneration, although this theory cannot be proven given the present state of knowledge.

Erlitou material culture shows links to earlier Longshan culture and later Shang material culture. Bronze workshops were present at the site; bronze artifacts and manufacturing equipment (such as crucibles) were numerous. Bronze vessels that held a fermented grain drink are typical. The Chinese tradition of jade manufacturing continues into the Erlitou phases; numerous ritual and decorative pieces have been recovered from Erlitou sites. Although there is no writing associated with Erlitou remains, potters' marks have been found on ceramics, and divination equipment (such as sheep scapula) has been found.

Shang Governance

The Shang dynasty is the first Chinese dynasty to leave written records. The records are not numerous and come in two forms. Oracle bones, the

remnants of Shang divination practices, which played an extremely important role in political decision making, provide crucial information about day-to-day governing. Oracle bone inscriptions also confirm that the last nine kings in the traditional accounts of the Shang did in fact reign in the order in which tradition holds. Small inscriptions on bronze are also used by scholars in the reconstruction of Shang history.

The name “Shang” refers to the ancestral capital of the first rulers of the dynasty. The capitals themselves shifted according to the political climate of the time. Kwang-Chih Chang has argued that secular capitals coexisted along with sacred capitals, although both types of power bases were linked to the Shang king. According to the traditional Chinese accounts, the last ruler of the Xia was overly swayed by an immoral concubine. Tang rebelled against this king, took control for himself, and founded the Shang dynasty. Ancient tradition holds that this happened around 1766 BCE. There is no corroborating evidence that this in fact took place; some scholars assume that there was no Xia dynasty, and most now believe that the these dynasties overlapped chronologically to some extent. Recent attempts to date the beginnings of the Shang dynasty are based on correlating archaeological dates with astronomical phenomenon recorded in the oracle bone inscriptions. Keightley suggests a date of 1544 for the first year of Tang’s reign. Similar dating techniques are used to identify the end of the Shang period. Keightley dates the end to 1045 BCE, which is later than the traditional end date of 1122 BCE (first argued for by a historian in the Han dynasty).

The historical traditions of the Shang kings come from the work of the ancient historian Sima Qian. This account can be difficult for modern historians to use since it appears to mix mythological and historical information. Sometimes the mythological components are obvious, such as the accounts of King Xie’s conception, when his mother swallowed an egg dropped by a flying bird. In fact, prior to the discovery of the oracle bone inscriptions, many scholars believed that the Shang was entirely mythical. It is now clear that Sima Qian’s work reflects a much more complex blending of historical data, Chinese religious belief, and political propaganda.

➤ THE LINEAGE SYSTEM

Wang Guowei, one of the most influential Chinese historians of the late nineteenth and early twentieth centuries, argued that one of the major steps in the development of the Chinese state was the institution of the lineage system (*zong fa*) by the Duke of Zhou, the brother of the founder of the Zhou dynasty. This was a system of patriarchal descent in which the family lineage was passed down through male family members. Eventually these lineages would get quite large, so younger sons might form new lineages. These new lineages were called minor lineages; the older lineages were referred to as major lineages. One of the most respected modern Chinese archaeologists, the late Kwang-Chih Chang, has argued that the beginnings of this system date to much earlier, to the Neolithic period. Chang argues that the spatial distribution of tombs in the Longshan culture reflects a patriarchal segmentary lineage system and that this has been a governing principle in Chinese society (and thus in Chinese political organization) throughout the period of the Three Dynasties and before.

—Kevin M. McGeough

The Shang government was led by a king who derived his authority from his relationship to the ancestors (especially royal ancestors but not entirely). He was the head of a patriarchal pyramid of authority whereby political relationships were conceptualized as filial ties. Shang succession is not entirely understood. Leadership passed directly from father to son, but the rationale behind which son became king is unclear. Some ancient accounts seem to complain about the chaos that ensues when the younger child is chosen to be king, suggesting that while the eldest son was the preferred choice, this was not always the case. The king was at the top of the pyramid, with his adult sons (princes) ranking slightly below him. These princes each headed their own minor lineages, often associated with particular geographic regions within the Shang kingdom. Below the king’s sons was another class of princes. These were members of royal lineages from before the time of the current king (the descendents of royal brothers who never became king). These other members of

the royal family were incorporated into the state structure as heads of minor lineages, owing formal obeisance to the king's ancestors (and thus by proxy to the king if not directly to him). These minor lineage heads may also have been local rulers who were not actually related to the king, but a fictitious relationship was represented as a means of incorporating them into the hierarchical structure of the Shang kingdom. Low-level local officials were also part of the Shang political system but were not necessarily part of the lineage system. Many of these people were powerful individuals within a local community who dealt directly with the state superstructure. Other officials were chosen by divination; their appointment to various positions was seen as ratified by the gods or ancestors.

Royal consorts were well-respected members of Shang society. These women were valued in Shang times for their ability to produce heirs, although enacting of powers beyond the reproductive realm seems to have been discouraged. In death, Shang royal women were highly honored; they became part of the so-called many mothers of the ancestor cult. Numerous individual queens were especially popular for veneration.

Western Zhou Governance

The Western Zhou has long been considered a paradigm for proper governance in China. The

early rulers in traditional accounts are seen as blessed kings who acted according to proper virtue and the will of the gods, ruling by what is called the Mandate of Heaven. The first of these virtuous rulers was King Wen, who reigned during 1099–1050 BCE according to the traditional accounts. In 1053, this king led the Zhou army through Shanxi Province, bringing his troops into too close proximity of the Shang capital. Territories that had been loyal to the Shang switched their allegiances to the Zhou, seemingly dissatisfied with the Shang leadership. Wen died before conflict with the Shang erupted, but his son, King Wu (who reigned during 1049–1043) began a campaign against the Shang, bringing his army to the Shang capital of Anyang in 1045. There he defeated the Shang army in battle and, with the suicide of the Shang king, became ruler of a large Chinese empire.

King Wu died two years later, and a succession crisis ensued. Precedent held that his oldest son should take the throne. However, Wu's brother Zhou Gong, better known as the Duke of Zhou, declared the king's son (later known as King Cheng) to be too young to rule and declared himself regent. It is difficult to understand precisely why this happened; it seems that King Cheng was in fact old enough to rule. Whatever the case may have been, other relatives of Wu rebelled against the Duke of Zhou and King Cheng, joining sides with surviving members of the Shang dynasty in the east. The Duke of Zhou and King Cheng traveled with an army to the east and put down this uprising, cementing governance over a vast region.

With King Cheng and the Duke of Zhou's quelling of the rebellion in the east, Zhou governance came to take on its more permanent form. Rather than ruling conquered areas directly like the Shang predecessors did, the Zhou kings invested royal family members, local elites, and even previous members of the Shang ruling houses over conquered territories. In the heyday of the Western Zhou, more than 100 separate territories were ruled by administrators established by the Zhou but without internal interference by the Zhou king. These rulers held specific ranks within the Zhou government and were expected to provide military service and tribute

but otherwise operated with relative autonomy throughout their particular regions.

Wu and the Rise of the Zhou

The origins of the Zhou dynasty are preserved in the legend-filled *Shujing* (*Classic of Documents*). Given the nature of this work, historians have difficulty determining the historicity of the near legendary figures discussed within. One such figure is Wu (Wuwang), supposedly the first king of the Zhou dynasty, who, if tradition can be believed, ruled in the mid-eleventh century. Before he established the Zhou dynasty, he was the ambitious leader of a small province on the western frontier of the Shang dynasty. He and his father (Wen, the Cultured King) formed alliances with many other frontier territories and defeated the last Shang king, establishing China's longest-lived dynasty.

During the twelfth century and earlier, the Shang rulers used the Zhou tribe on the western frontier as a buffer against often-aggressive nomadic people who lived farther west. The Shang conferred titles on the militant Zhou leaders and did their best to cultivate good relations with them. By the middle of the eleventh century, Wu's father, King Wen (Wenwang), who had been given the title "King of the West" by the Shang, began plotting against the increasingly unpopular Shang ruler, Zouxin. Wen died

THE DUKE OF ZHOU

In later traditions, Wu's brother, the Duke of Zhou, was a figure of great admiration. According to tradition, when Wuwang was close to death, the duke appealed to heaven that his life be taken instead of his brother's. The appeals did not work, and Wu died anyway, yet the records of the duke's appeals were sealed in a metal box as proof of his steadfastness toward his brother, the king. These records, tradition holds, came in handy later when the duke was accused of having plotted against his brother. The sealed records proved his innocence, and rather than taking the throne himself, he instead supported Wu's underage son.

—Kevin M. McGeough

during one of his many attacks on the Shang peoples. Wu became the leader of the Zhou and continued his father's efforts at forming alliances with other tribes and plotting against the Shang. He gathered a large military force with the assistance of eight other border states to attack the Shang capital.

The attack, aided by mutinous Shang soldiers who were unhappy with the corruption of the Shang court, was a great victory for the Zhou. They sacked the capital, Anyang, and Zouxin committed suicide. Wu founded a new capital at Xian (known earlier as Chang'an) and began consolidating and governing a vast new empire that stretched from Inner Mongolia in the north to the Yangtze River in the south and from the Gansu Corridor in the west to the East China Sea.

Wu's task of establishing a new dynasty was justified by the Mandate of Heaven, which current scholars suggest was an ideology created by the Zhou to justify their overthrow of the Shang. According to that belief, a king held power only as long as he was virtuous. Therefore, when a king was overthrown by rebellion or defeated by an outside force, it indicated that Heaven had revoked the mandate and bestowed it upon someone else. The Shang people had become increasingly unhappy with the Shang king, so when Wu defeated him the people viewed that action as proof of a new mandate of Heaven

THE DUKE OF ZHOU'S THOUGHTS ON GOVERNANCE

Many classics of Chinese literature were composed during the Western Zhou period, some of which were credited to the early virtuous kings although they were actually written more than 250 years after these kings died. The *Shang shu* is credited to the Duke of Zhou and may actually have been written by him. The language of some of the poems contained within is an archaic form of Chinese that dates to early in the Western Zhou. In these poems, various discussions of political philosophy and understandings of government are laid out, giving modern readers direct access to Zhou political doctrine.

—Kevin M. McGeough

being bestowed upon Wu. The Duke of Zhou, one of Wu's brothers who had spent time in the Shang court, aided Wu's ascension to the throne by convincing many of the Shang nobles to support Wu.

Although he was known as a strong and stern leader—he gave himself the title “Martial King”—Wu knew he would need the help of many Shang officials around the empire if he wanted to maintain control over his vast new territory. His brother, the Duke of Zhou, allowed many of the Shang officials to stay in their administrative posts and named his fellow Zhou to fill others. He even allowed the heir of the Shang throne to remain as the nominal ruler of Anyang, but he assigned two of his brothers to carefully monitor Shang activities. Wu parceled out subordinate states to his loyal lords, who ran them on behalf of the Zhou dynasty. That method allowed the Zhou to control the vast territory in a way that the Shang could not.

Wu revealed his virtuous character, earning him the admiration of future Chinese kings and philosophers, when he refused to take credit for the founding of the Zhou dynasty and gave the honor to his father instead. Wu recognized that although he had defeated the Shang in battle, the groundwork for the Zhou victory had been laid by generations of Zhou leaders.

Wu did not have the opportunity to fully consolidate his power because he did not live long after defeating the Shang. He died circa 1104 and was succeeded by his son, King Zheng. Leaving the throne to his son rather than his brother was a break from Shang tradition; future Chinese dynasties would follow that practice. Since Zheng was very young when Wu died, the Duke of Zhou acted as ruler for many years. His guardianship laid much of the foundation of the Zhou dynastic success through incorporation of a system of feudalism upon which later Zhou kings would expand. Many future Chinese rulers and thinkers looked back to the reigns of Wu, the Duke of Zhou, and Zheng as China's Golden Age and paid great tribute to the virtue and wisdom they exhibited as kings.

Introduction: The Arts and Ideologies of Governance

In the period from 4000 to 1000 BCE, rulers did not govern according to the whims of the people. Rather, the people were governed

by the whims of their rulers, whether those rulers were kings, priests, or aristocrats. A king was not expected to justify his tax expenditures to

the citizens and usually did not need to explain his rationale or get permission from his advisors before making decisions. Instead, in those areas where strong leadership arose in Era 2, the justification for the ruling elite's authority came from three sources: divine approval, military might, and economic clout.

The clearest statements that justified political leadership in Era 2 were those statements that the leader had been chosen by the gods to rule. This was expressed most strongly in Egypt, where the king was seen as the offspring of the gods and thus semidivine. In Mesopotamia, Anatolia, and China, the gods could grant leadership but could also take it away. Ancient Mesopotamian, Hittite, and Chinese historians explained the rise and fall of political dynasties by arguing that those leaders had gained and subsequently lost favor with the gods. The interpretation of dreams and various divinatory practices were used as means of understanding the will of the gods. Those who could interpret dreams and signs in this manner wielded much power at many ancient courts, since they could inform the king about the will of the deities and thus influence policy.

Military and coercive power also lay at the heart of political power in the ancient world. Kings gained territory through armed conflict; a military presence (or the possibility of a military presence) kept those territories from revolting. Royal monuments can be found throughout the ancient Near East depicting the king's military strength (often idealized as images of the king hunting) and commemorating important battles. Although most would not have been able to read the accompanying inscriptions, all would have been able to interpret the images of the valiant king's army brutalizing its opponents. These messages would not have been meant to simply convey that the king and his army should be feared. The king was also depicted as bringing order to chaos, bringing law to lawlessness, and providing security from danger.

The economic clout of ancient royalty also manifested itself in the arts used to justify governance. Elaborate palace complexes (such as that at Mari), enormous royal tombs (such as the pyramids at Giza), and other architectural marvels

acted as tangible demonstrations of the royal power to command resources and labor. In and of themselves, these monuments demonstrated that the rule of the king was natural and unquestionable. The possession of royal-style objects allowed local elites to aspire to royalty; by being allowed to use items like those of the king or that were given as gifts by the king, these local elites were able to distance themselves from other members of the community. At the same time, this reinforced the support of the king by wealthy members of the community.

—Kevin M. McGeough

Debating Ancient Imperialism

Modern historians debate whether or not imperialism is a valid concept for understanding the relationships between polities in ancient times. Certainly the level of interaction between polities (and thus the level of control held by the dominant group) was significantly less in antiquity than in more recent historical times. Yet without a doubt, from the origins of the first states relationships of inequality developed between more powerful and less powerful polities. When thinking about ancient imperialism, it is thus best to avoid thinking of it in modern terms. Ancient imperialism should be considered an institutionalized relationship of imbalance between a dominant area and a subordinate area.

Ancient imperial relationships were usually construed along geographic lines. The dominant area was considered the core, the center of the empire. The subordinate area was considered to be peripheral, located on the margins of the core area. For example, in ancient Egypt, the region that extended from the delta in the north along the Nile River to the first cataract in the south was considered the center of Egyptian civilization. Yet at many times, Egypt controlled Nubia to the south and Syria-Palestine to the northeast. However, these areas were always thought to be distinct from Egypt proper, peripheral parts of the larger empire.

These core and periphery relationships are always uneven. The core benefits at the expense of the periphery. Benefits to peripheral regions

may emerge from the relationship, but the core is the center of decision making and ideally (although not always in practice) the economic beneficiary of the imperial relationship.

The motivations behind the establishment of an imperial relationship are not always consistent. Often an empire formed almost accidentally, a by-product of military activities engaged in for security purposes or to gain wealth. Resource extraction was another common goal; a core area would occupy a peripheral area in order to gain access to valuable resources unavailable locally.

There were many justifications for the conquest of foreign lands as well as for the structured inequality between the core and periphery. The most common justification was that there need not be a justification; in Egypt's case, the Egyptian worldview saw Egyptians as a better class of human than any other group. Historical precedent was also used to justify the conquest of foreign lands, based on claims that the lands once belonged to the conquerors or that the foreigners had a tradition of aggression. The king is often portrayed as a force of order, bringing that order to the chaotic foreign lands. Divine favor was used to understand why one group dominated another. It was not that one group's gods were stronger than another group's (there are no examples of this kind of logic preserved from ancient times); rather, it was that the gods withdrew their support from a particular group.

Royal Inscriptions from Mesopotamia

A Mesopotamian king was expected to ensure the welfare of his subjects, protecting them against aggressors; undertaking public works and promoting trade, agriculture and industry to bring prosperity; supporting the weak and disadvantaged; and upholding justice. He also played a major role in religious rites, mediating between the gods and his people.

In their inscriptions, kings informed the gods of their pious, appropriate, and successful activities following divine wishes; they also addressed the public at various levels and for future monarchs, offering themselves as models of righteous behavior. Success was in itself indicative of legitimacy and divine approval. Nevertheless, royal inscriptions might offer an apologia for unorthodox actions: for example, usurpation was justified by emphasizing the misdeeds of the deposed ruler and the need to restore the status quo. Often stories from history were reworked to give the sanction of tradition to a king's present actions. Those without direct access to the message—for example, villagers—eventually became party to it through hearsay and gossip. Thus, the ordinary citizen gained confidence in the divinely supported actions of the monarch. Like all propaganda, however, what the kings claimed was not always true.

The first historical documents, known from the Early Dynastic (ED) II–III period, were brief inscriptions on votive offerings and buildings, naming the royal donor. By the mid-third millennium, however, narrative texts were being written, explaining and justifying the king's actions and demonstrating that he was acting in accordance with divine will. Around 2400 BCE, Enmetena of Lagash gave an impassioned account of the long-running border dispute between Umma and Lagash. Some 50 years later Uru-inim-gina, also of Lagash, lauded his own efforts at reform and delivered a tirade against Lugalzagesi of Umma, who had sacked Girsu.

From the Akkadian period onward bricks incorporated into public buildings were often stamped with the name of the king who had commissioned them and information about the structure such as the names of the temple, the

deity to whom it was dedicated, and the city in which it was built. Votive clay nails inscribed with the name of the king and a dedication or a longer text were also incorporated into temples.

The Akkadian kings produced rich propagandist inscriptions, describing their wide-ranging conquests and power and the prosperity of the land under their rule, with merchants coming to their city, Agade, from far across the sea. In contrast, in the period following the fall of the Akkadian empire, Gudea of Lagash was more concerned with recording his pious works. A two-cylinder poem describes Gudea's dream of Ningirsu's request that he construct a marvelous temple and his endeavors to bring together all the choice materials needed for the task: timbers from the Cedar Mountains, red stones (agate or carnelian) from Meluhha, gold, and silver. In their royal hymns the Ur III and later Babylonian kings were also more interested in proclaiming their efforts for the welfare of their people than their conquests. Many third millennium-inscribed monuments, stelae, and statues from the courtyard of the Ekur in Nippur were assiduously copied by Old Babylonian (OB) scribes, complete with catalog details describing the monuments themselves.

In the north, kings such as Shamshi-Adad focused their inscriptions on their military achievements. Later Babylonian kings included fuller details of their conquests in their inscriptions but also celebrated praiseworthy aspects of their reigns, such as the construction of canals. Assyrian kings, from Adad-Nirari in the early thirteenth century, developed military inscriptions into longer first-person narratives of their achievements, those of Tiglath-Pileser I and of kings from the late eighth century onward being written because of their length on large clay prisms; stone stelae were also used in the ninth and eighth centuries. These records of conquests and triumphs were written with a dated section dealing with each campaign; later editions contracted the account of the king's earlier campaigns so as to make space for the most recent. Late in a long reign, the annals might omit some campaigns or run several together. These were written as dedicatory inscriptions to be placed in the foundations of buildings, a traditional practice. Royal texts were often written not for the human

reader but for the deity to read and approve. The deeds of Assyrian kings were also celebrated in epic poems and in the inscriptions accompanying the forceful reliefs of the triumph of Assyrian might, carved on the palace walls to impress all who saw them. Kings boasted not only of military deeds but also of their feats of engineering, discovery, and magnificent construction.

Egyptian Kingship—Order Fighting Chaos

Much of ancient Egyptian ritual, religious thought, and royal ideology was inspired by an urgent need for order to triumph over chaos. This unending and unrelenting demand stemmed from a universal thread present in Egyptian cosmogonical accounts. While Egyptians came to embrace a variety of creation accounts (accompanied by a number of creator figures), all of these traditions reflected a concern that order was in danger of being overcome by chaos.

Universally, Egyptians acknowledged that creation was the result of the organization of chaotic materials. Immediately after creation, the cosmos was in a perfect and pristine state, with everything correctly ordered. In this state the gods, as the original kings of Egypt, lived on earth with mankind. In each account there came a time when some type of rebellion—whether it

be the rebellion of Seth against his brother Osiris, mankind against Re, or Aophis against the gods—introduced chaos into the cosmos and caused the gods to withdraw from the earth. The resulting condition was one in which chaos was constantly impinging upon order, and only the king could stem the tide. It was the primary duty of the king to safeguard the cosmos by destroying chaos and establishing order. This was an urgent, unending task.

A number of texts illustrate the care that kings took to show that they were fulfilling their responsibilities in this regard. For example, Amenemhet I associated himself with the divine as well as demonstrated his importance to Egypt when he claimed to have appeared as Atum (the creator) himself, setting in order that which he found decaying. Ancient scribes praised Thutmose III by claiming that he reinstated the conditions of the mythological time when the god Re was king. It is clear that incumbent kings were obligated to return conditions to the orderly state of the Golden Age when the world was new and pristine.

In order to do this the king had to fulfill his primary duty: to destroy chaos and replace it with order. One Pyramid Text informs us that order is in the presence of Re on the festival of the first day of the year. The sky is content, and the earth is in joy because they have heard that the king put order in the place of chaos. The prophecies of Neferti state that the king will cause order to return to its seat, and chaos is driven out. The king's role in this process is probably made most explicit in a liturgical text: Re has put a king on the land of the living so that he may bring about order, so that he may destroy chaos.

Much of the ideology and iconography of kingship revolved around this concept. It seems that all of the offerings that the king gave to the gods were tokens of offering order, and texts make it clear that only he had the ability and obligation to regularly offer order to the gods. It is likely that all of the scenes of the king smiting enemies, conquering in battle, hunting hippopotamus, or netting wild birds are symbolic of his conquering chaos. In some rituals he offered order to the gods as he concomitantly used the Wedjet eye to destroy chaos. Even the very act of

becoming king was tied up with destroying chaos and restoring order. The death of the previous king was associated with the death of Osiris, an event that introduced chaos into the world. As the new king ascended to the throne, he always stylized himself, like Horus, as having found the land in a chaotic state, a condition that his assumption of power corrected.

Imperialism and Ancient Art

Empires are formed when one state finds it economically and politically expedient to conquer and rule formerly independent regions or states. All empires rely on various means to appease, assimilate, and otherwise control the different regions under their control. In these attempts, the visual medium of art is a powerful tool. Art and monuments are a very public means that a ruler can assert his control, ideology, and ambitions on a large audience.

We have numerous examples in the art and archaeology of the ancient Near East and Egypt of how royal art reflects the imperialistic aspirations of a particular ruler. This is especially true of the later Assyrian and Persian periods but can be traced all the way back to the third millennium BCE. Take for instance one of the earliest Egyptian historical documents. This is the Narmer palette, a carefully carved stone cosmetic palette. On this luxury object the message

is clear. The pharaoh is supreme ruler of both Upper and Lower Egypt and can conquer all that stands in his way. The king is shown larger than everyone else, occupying his own space. His pose, in the midst of striking his enemies, presents the king as eternally vigorous and victorious.

In Mesopotamia, many kings set up public stelae in city centers. One of the best-known examples and a masterpiece of early Mesopotamian art is the Stele of Naram-Sin. These stelae served as public reminders of the king's role. In the early Sumerian period they showed images of the king as conqueror and builder, but by the time of Hammurabi in the Old Babylonian period there was a new message. Hammurabi set up a stele engraved with his set of laws for all to see. At the top of the cone-shaped stele is a two-foot-high image of Hammurabi receiving the rod and the ring of kingship from the sun god Shamash. The image is a canonical Mesopotamian presentation scene in which a ruler stands before a god. Here, however, there is a new rapport between king and god. The two face each other at virtually the same eye level so that sustained eye contact is possible. The rest of the seven-foot monument is covered with the inscription of Hammurabi's famous law code. The image of the laws in conjunction with the presentation scene complement one another, both conveying the one message that Hammurabi is a wise and just king.

The Hittites in Anatolia were also adept at employing art in their imperialistic goals. Along their border regions, the Hittites carved images of the king and gods on natural rock faces. In this way they were able to mark the boundaries of their state and bring to the farther regions of their empire images of the king. By setting up these eternal monuments to the king and the Hittite worldview, the Hittite kings attempted to unify the far reaches of their kingdom.

The Stele—State Monuments and Visual Power

In Mesopotamia and Egypt, rulers erected upright, often freestanding stone monuments called stelae to commemorate specific accomplishments or events from their reigns. Decorated with pictorial and written accounts of the event in question, these monuments were frequently dedicated to the gods and were set up in temples and, in the case of Egypt, along territorial boundaries. They served not only to proclaim the king's glory and fulfillment of his royal responsibilities but also to indicate divine support for his reign, often through the depiction of the gods or their symbols with the figure of the king. From the Early Dynastic period in Mesopotamia and the Middle Kingdom in Egypt, most royal commemorative stelae were cut in a standard rectangular shape with a rounded top.

The history of royal stelae in Mesopotamia stretches over three millennia, from the Late Uruk to the Neo-Assyrian periods. Despite significant shifts in style and execution during this time, there is a remarkable continuity in the subjects they portray, which represent the king engaged in uniquely royal activities: he hunts, wins

➤ WHAT IS A STELE?

A stele is an upright, inscribed stone slab or pillar with a curved top; it is used as a gravestone, monument, or marker. Common throughout the Near East and Mediterranean, early stelae, which date from the second millennium BCE during the First and Second dynasties of Egypt, relied solely on inscribed or painted images to communicate meaning. People began incorporating text into stelae as writing became more widespread in the ancient civilizations. Some of the more famous stelae include inscriptions detailing the Code of Hammurabi and the Lhasa rdo-ring (Long Stone of Lhasa) in Tibet, which dates from the early ninth century CE. Stelae were also used in the Mayan civilization.

—Kevin Marsh

THE VICTORY STELE OF NARAM-SIN

Victory Stele of Naram-Sin, First Akkadian dynasty. (Gianni Dagli Orti/Corbis)

This limestone monument commemorating Naram-Sin's victory over the Lullubi tribe of the Zagros Mountains is one of the masterpieces of Mesopotamian art. The surface of the stele is treated as a single visual field rather than being divided into the registers characteristic of older monuments and depicts the king triumphantly ascending a mountain beneath the symbols of the gods, his enemies trampled beneath his feet. Naram-Sin is distinguished not only by his size and lofty position, being larger and standing higher than that of any of the other figures, but also by his horned helmet, a headdress reserved for gods. His soldiers follow in orderly formation, contrasting sharply with the scattered and defeated enemy.

—Karen Sonik

battles, builds temples, and stands in the presence of the gods. The late fourth-millennium Warka Stele, an uninscribed basalt boulder, depicts the priest-king hunting lions, strongly associated with kingship throughout Mesopotamian history, with a spear and bow. The Early Dynastic Stele of Eannatum, the first to combine images with text, celebrates the victory of Lagash over Umma and includes an anthropomorphic depiction of the god Ningirsu holding the soldiers of Umma in a net. A distinct shift in royal ideology occurs under the Akkadian empire, with a stele of Sargon depicting him, rather than a god, as ultimately responsible for victory: it is now the king who holds the net containing his enemies. On the slightly later Stele of Naram-Sin, the first Mesopotamian king to be deified during his lifetime, this shift is even more apparent. Naram-Sin is not only the paramount figure of the composition but also wears divine regalia. The gods are represented only by their symbols, which are placed above his head.

The anthropomorphic form of the gods reappears on the Ur III Stele of Ur-Namma, which portrays the king as temple builder, and the Old Babylonian Stele of Hammurabi, which records that king's famous law collection. In the later periods, however, the gods are again commonly represented by their symbols in scenes with the king.

Egyptian royal commemorative stelae had a similarly long history and comparable purpose to those of Mesopotamia, existing alongside the predominantly private funerary stelae from the time of the Old Kingdom. They generally recorded such events as military victories, successful resource-gathering expeditions, construction projects, and dynastic marriages, although some also published royal decrees or served as boundary markers. Notably, while the events recorded on these monuments are not always accurately presented, being intended to reinforce the glory and invincibility of the Egyptian pharaoh, gods, and people, some of them have made significant contributions to our reconstruction of ancient history. Among these are the Seventeenth Dynasty Stelae of Kamose, which record clashes with the Hyksos (the foreign rulers of North Egypt), the Eighteenth Dynasty Restoration Stele of Tutankhamen, which proclaims a return to the

traditional Egyptian religion after the reign of Akhenaten, and the Nineteenth Dynasty Merneptah Stele, which is inscribed with the earliest known reference to Israel.

International Style in the Late Bronze Age

In the Late Bronze Age (ca. 1500–1200 BCE) the eastern Mediterranean region was ruled by various states, both large and small. These states were in close contact with one another, sending each other letters and gifts and marrying one another's daughters. Egypt was particularly powerful during the earlier part of this period and conquered most of the small states in the region now known as Israel-Palestine and northern Syria. During this age of contacts and international diplomacy, a new artistic style arose among the luxury arts of these kingdoms that reflected this new age of internationalism. Scholars have called this the "International Style," for these objects combine different regional styles and motifs, giving them an international flavor. Some see this as the natural outcome of the increased trade and diplomatic contacts of the Late Bronze Age. Others suggest that the mixing of different styles is a deliberate attempt to embrace a culture of equality and brotherhood reflected in the art.

The International Style is restricted to luxury objects made out of the most precious materials, such as gold, silver, or ivory, and these

were in all likelihood made specifically for the royal courts. They are almost exclusively found in either palaces or wealthy tombs. The styles combine features that are generally associated with Egypt, the Aegean realm, or the Levant. They usually revolve around the same themes, that of elaborate vegetal motifs, standing gazelles or goats, hybrid animals, and hunting scenes. These are all very old themes in Mesopotamia and Egypt but became integrated into the artistic repertoire of the eastern Mediterranean world. The objects classified as international represent these themes in similar ways and draw inspiration from the way they are depicted in several areas.

A good example of this new style is a silver bowl found in a tomb at Enkomi. The bowl is in the form of a local Cypriot ceramic vessel, so it was almost certainly made on Cyprus itself. The bowl is silver, but it includes flowers and bulls' heads of ivory and paste done in a technique used by Minoan and Mycenaean metalworkers. The frontal bull with horns was a common Minoan religious symbol. This type of repeating pattern of bulls' heads and vegetation also has parallels farther east in Mesopotamia.

The ivory throne pieces found at Ugarit are another example of the style. Certain aspects of the imagery clearly reflect Egyptian influence. These include the theme of the suckling nurse as well as the style of dress of some of the figures, which is purely Egyptian. On the other hand, it is clear that Syrian artisans manufactured the bed in Syria because of certain local features. Some of the figures in the scene wear local Syrian dress, and certain elements of the representations, such as the type of sword one of the figures carries, are non-Egyptian. The palmettes that surround these figures are a recurrent image in this category of objects.

Another object that well represents the international style is the lid to an ivory box found at Minet el Beida, near Ugarit in Syria. The details of this piece—her dress, the way she is sitting, and her hairstyle—reflect Mycenaean representations, but the overall theme is a Mesopotamian one, a mistress of animals. This is a good example of how cultures freely adopted motifs and ideas from one to the other in this period. Although this was probably made in either Greece

➤ EGYPTIANIZING ART

Egyptian art had a particularly strong influence on the luxury arts of Syria-Palestine. The artists of this region made direct imitations of Egyptian objects but also utilized specific Egyptian elements in original works. In the first example, residents of Syria-Palestine during the fourteenth and thirteenth centuries BCE particularly favored small cosmetic utensils made out of ivory, a very expensive material, although in Egypt these were generally made from wood. Local artists fashioned Egyptian-style ivory spoons, boxes, hairpins, combs, boxes, and figurines. Small boxes shaped like a duck were especially popular.

Toward the thirteenth century BCE local Syro-Palestinian artists created Egyptianized art. Artists did not slavishly copy Egyptian styles but rather incorporated Egyptian imagery such as the sphinx and the lotus or the smiting king into larger compositions. In Syria-Palestine this trend spanned the Eighteenth through the Twentieth dynasties, namely between the fourteenth and twelfth centuries BCE. This is exactly the period when Egypt reasserted its control over the Levantine coast. In fact, it was common practice for the Levantine rulers to send their children to be raised at the Egyptian court to prepare them for the throne. This close familiarity of the elite with Egyptian culture may be one of the reasons that Egyptian-style goods were so popular. It is also true that Egyptian culture, the dominant political power in the region, became a status symbol for Syrian elites as well as a way of demonstrating allegiance to the Egyptian overlords.

—Susan Helft

or Cyprus, the motif of the mistress of animals would have appealed to peoples in the east where it was found who were already familiar with Mesopotamian traditions. One of the main features of this internationalizing tendency is that these objects could appeal to a very wide audience of people, both in the east and west. This also helps to explain their wide distribution from Greece to Syria-Palestine and Egypt.

These luxury objects from the Late Bronze Age eastern Mediterranean demonstrate the extent to which artists and artistic motifs traveled

freely among the political elite at that time. Many of these objects draw from an international repertoire of motifs that these different regions contributed to. These include the spiral and the flying gallop pose from the Aegean, the griffin, the sun disk and the hero in combat from Mesopotamia, and the sphinx and nilotic scenes from Egypt, to name a few. The pieces that show the most hybridization and synthesis of styles and motifs come from Cyprus and the Levant, both crossroads regions with highly cosmopolitan peoples. There is less of a synthetic tendency in Egypt or Greece, although they too participated in these artistic exchanges. The use and distribution of these objects became a way of belonging to a particular international class of wealth and power. The value of the material itself and the very cosmopolitan flavor of this style of objects showed that the owner had access to both wealth and foreign markets and ideas.

The Zhou and the Mandate of Heaven

The Mandate of Heaven (*tianming*) illustrates important principles about Chinese religion and politics from the early Zhou (Chou) era in the eleventh century BCE to the end of China's imperial dynasties in the early twentieth century CE. Although scholars' records of Shang religion in the second millennia BCE are limited, it is clear from oracle bones and inscriptions on bronze vessels that the responsibilities of the Shang kings intertwined political and religious roles. Sacrificial offerings to gods and divine ancestors were followed by divination practices using oracle bones. The divinations guided decisions of state often with simple yes and no questions asked of gods and ancestors with regard to whether hunting, travel, planting, crops, warfare, and other affairs would be auspicious. Religious and political dimensions of this pivotal role played by the king were fundamentally indistinguishable. However, sacrifice served as a system of exchange without a clear moral element evaluating the king's virtue.

Zhou religion added this moral dimension while still maintaining the king's pivotal religious and political role. Tian (T'ien) replaced Shangdi (Shang-ti), the high god of the Shang. There is indication that Tian, typically translated as "heaven," originally may have been a particularly exalted divine ancestor of the Zhou. Early records describe Tian as a high god closely connected with the Zhou rulers and interested in their activities and their virtue. The title "Son of Heaven" (*tianzi*) for Zhou kings demonstrated the close link between the highest deity and the dominant ruler. While this term reinforces the idea that Tian may have been interpreted as a divine ancestor of the Zhou, a "father" whose descendant now rules, it is more certainly and influentially a designation for the ruler who is supported by the Mandate of Heaven. In fact, this sense of a mandate intentionally removed the right to rule and the link to the divine from the confines of a single hereditary lineage. The mandate instead connects kings, gods, and the sanction to rule through morality with the explicit warning that the mandate can be revoked from one lineage and extended to a more worthy royal

➤ TIAN—HEAVEN

Tian has encompassed a range of meanings in Chinese religion. Early Zhou rulers referred to their high god as Tian. This thus became the dominant name for the high god displacing Shang Di (Shang-ti), the high god worshiped by the Shang kings whose rule fell to the Zhou. Tian was portrayed as involved and interested in human activities. The relationship with this personified high god suggests that Tian may have been an especially exalted divine ancestor of the Zhou. In any event, Tian's close attention to earthly affairs included a moral component absent in Shang Di. Over time, Tian became decreasingly personal and gained connotations of heaven as an abstraction for god, as the realm of the gods, or even as nature more generally. The idea of securing and maintaining the Mandate of Heaven (*tianming*) is in connection with the sense of heaven as a moral agent and powerful enforcer of morality capable of ending the reign of the corrupt and supporting the rule of the virtuous, the Son of Heaven (*tianzi*). Heaven, in complementary juxtaposition with earth, also became synonymous with the yang element or phase in yin-yang cosmology. As such, Tian is the name given to the trigram of three yang lines, and along with creativity it is a dominant association of the pure yang hexagram of six yang lines in the Yijing (I-Ching). Earth remains its complement as the trigram of all yin lines and a main association along with receptivity for the pure yin hexagram. This sense of heaven as the yang counterpart of earth in the natural order or pattern is further reinforced by important state ceremonies. Chinese emperors until the fall of the last dynasty in 1911 conducted state rituals such as the Sacrifice to Heaven performed on the Altar of Heaven (*Tiantan*) at the winter solstice. This ritually enacted an offering to heaven and a catalyst to stimulate the natural cycle back in the direction of yang just at the seasonal extreme of yin. Naturally, a complementary Sacrifice to Earth would have been performed at the summer solstice when yang forces peaked and the emperor intervened to stimulate yin.

—John Harding

line. Historian Benjamin Schwartz asserts that regardless of whether or not Tian and Shangdi were distinct gods, the Zhou founders declared Tian to be the same high god, Shangdi, who now favored them. This assertion was used as evidence of the mandate theory as opposed to a more static structure with a high god inexorably tied to one ruling lineage.

Heaven, as a personal deity—and later as a more abstract concept of the divine, the abode of the divine, or even as nature—was invested with a moral will and authority to support a virtuous ruler, heaven's son, or to bring down a degenerate ruler or dynasty who had lost the mandate. This created religious justification both for wielding political power and for usurping political power. According to this logic, the very act of overthrowing the Shang suggests that the Shang lost the mandate. Zhou rulers interpreted heaven's withdrawal of the mandate as a result of what they described as the dissolute practices and ritual neglect of immoral late Shang kings. The Zhou rulers' mandate, on the other hand, was confirmed by the fact of their rule. Because heaven's support of their reign was contingent upon their own virtue, the virtue of sage rulers became a preoccupation from Zhou times onward.

Of course, one can argue that the Zhou concept of the Mandate of Heaven was a political expedient to use religious ideas to justify usurping the Shang and to legitimize their own rule as morally superior and consistent with divine will. It served these ends, but it cannot be brushed aside as merely a political expedient. Early Zhou rulers, including the famous paragon of virtue, the Duke of Zhou, acknowledged that they should not take their mandate for granted, as heaven could bring destruction upon them just as it had on the Shang before them. Religion and politics remained closely intertwined with the Mandate of Heaven as a central component to religious and political philosophy for thousands of years beyond the Zhou overthrow of Shang rule. The late Zhou provided especially fertile ground

for philosophical, political, and religious speculation as many of the great Chinese philosophers sought a return to order, harmony, and righteous rule in a chaotic time. Some struggled with the meaning of this mandate and the will of heaven, as it did not appear to them that a new virtuous ruling lineage had received a mandate or risen to power in place of failing kings and disintegrating rule. Interpretations of this theory and the role of heaven ranged from an active and discriminating arbiter of morality to impersonal natural cycles evident in patterns and phases in the heavens, on earth, in the human body, and in the body politic. Despite this later range of interpretation, the Mandate of Heaven remained important, as philosophers and rulers alike appealed to heaven's authority for aligning and regulating earthly rule.

Economics and Trade

About 4,000 years ago, Taram-Kubi, who lived in the Mesopotamian city of Assur, wrote a letter to her husband, Innaya. Innaya was making a living as part of the Old Assyrian trade network and was then residing in Anatolia. In her letter, Taram-kubi states that she cannot find the bracelets that he had left in the house in Assur for her to buy food with. She further informs him that there is a famine in the city and that she does not have the ability to purchase grain, let alone live the extravagant lifestyle that he must have accused her of in a letter that was not preserved. She mentions some other business matters and concludes by asking him why he listens to slander about her and why he writes her such irritating letters! Letters such as this allow scholars to reconstruct the economic lives of ancient Mesopotamians, from complex business matters to day-to-day living.

Even with interesting evidence such as this, questions still remain. Were the motivations of these Old Assyrian traders, such as Innaya—who lived far away from his none-too-pleased wife—really the accumulation of profit? It is hard to understand the evidence in any other way. Yet in many ways, the Old Assyrian situation seems unusual for this era, where the accumulation of capital for its own sake seems to be relatively rare. These issues are at the heart of one of the truly difficult problems facing the study of ancient economy: to determine how similar ancient economic behavior was in comparison to economic behavior today. This is one of the least agreed-upon issues in ancient economics, partially due to difficulties in interpreting the evidence and partially due to current ideological biases.

In less ideologically loaded situations, this problem is still apparent, rooted in what has come to be called the formalist-substantivist debate. Formalists believe that there are universal (or formal) laws that govern all human economic behavior and believe that ancient people were motivated by the same urges that motivate people today. Formalists typically use analytical methods derived from modern economics (such as supply and demand curves) to understand economic behavior, although this is often difficult given that only rarely does enough information survive to allow these methods to be properly used. Formalists see market exchange, where individuals exchange goods without expectation of further social relationships, as the dominant mode of economic behavior. Substantivists believe that there are no universal laws that govern economics and that economic behavior is contingent upon the particular culture. They believe that an ancient economy could have been dominated by any number of types of exchange, such as gift giving (where the building of relationships is very important), redistribution (where a centralized authority collects everything and then redistributes the

goods among the community), and market exchange (such as that presupposed by formalists). As it stands, there has been no satisfactory conclusion to this debate, forcing scholars to work from one or the other of these perspectives.

The complicated business ventures of traders such as Innaya were far from the norm for this time period in world history. Most of the people who lived during this time were more concerned with basic subsistence, such as having enough food to eat. Many households, even

The complicated business ventures of traders such as Innaya were far from the norm for this time period in world history. Most of the people who lived during this time were more concerned with basic subsistence, such as having enough food to eat.

those found in large urban centers in the larger states (such as Egypt and China), were self-sufficient. Most engaged in some kind of food production, whether it was agricultural/horticultural, animal rearing, or some combination thereof. In regions where cereals (such as grain or barley) were grown, each household also had the equipment necessary to engage in secondary food production (e.g., grinding equipment). Clothing was mostly manufactured in the home; textile manufacturing was

one of the most time-consuming chores of everyday life in the ancient world, and thus clothes were tremendously valuable. In Mesopotamian myths and the Homeric tales, clothes are among the most valuable gifts that could be given. In some regions clothes were used as a form of payment, such as at the city of Ugarit on the Syrian coast, where palace workers received payment in wool. Some tools were also made in the household, depending on the complexity and availability of raw materials.

Sometimes, members of a household were able to gain specialized skills, allowing them to produce goods or perform services that could be traded for other goods or services. This ability to produce a surplus was fundamental to any participation in an exchange relationship: a house had to produce more than it needed to survive. If there was a surplus it was probably meager at best, especially after taxes were collected. Some scholars believe that the drudgery of work, the difficulty of trading and storing goods, and the lack of anything to trade for limited the amount of surplus production that a household could produce discouraged the accumulation of excess goods. Other scholars feel that ancient motivations were the same as modern ones and that the urge to make a profit is fundamental. Much of this must have actually depended on the personalities and skills of the members of individual houses, and as with many archaeological debates, the truth probably lies somewhere in between.

■ Introduction: From Hunting and Gathering to Farming—The Development of Social Complexity

The transition from hunting and gathering/scavenging subsistence regimes to agricultural subsistence regimes is usually archaeologically “visible” through an increase in material culture best suited for sedentary (non-mobile) lifestyles. Houses are made out of more permanent materials and are suitable for year-round habitation as opposed to seasonal habitation. Since hunting and gathering groups tend to divide into smaller subgroups during certain seasons, their habitation sites are often much smaller and more ephemeral than year-round sites. Once people shift to permanent houses, they tend to accumulate more “stuff.” People on the move tend to only accumulate necessary objects, usually objects that are well suited for carrying over long distances. Sedentary groups do not have to worry about constantly lugging their possessions around with them, so they are not as careful to discriminate about what they acquire. A marked increase in the utilization of pottery is often a sign of an increasingly sedentary society. Pottery can be heavy to transport and is easy to break but has a wide variety of uses in the storage, production, and consumption of agricultural products.

While the practices that go with this transition (as well as the types of archaeological evidence left behind) are similar worldwide, the ways that scholars describe them are not. Archaeologists who work in the “Old World” (basically everywhere but the Americas and Oceania) usually call this transition the “Neolithic.” The term “Neolithic” is used to refer to a wide variety of time periods, differing from region to region. “Neolithic” is used when a region exhibits these characteristics of the transition to settled agricultural practices. In Europe, the Near East, and East Asia, scholars widely accept the use of this term. Archaeologists working in Africa debate the suitability of this term, and many prefer not to use it. Archaeologists who work in North America rarely use this term, since the system of nomenclature does not have much utility in the description of ancient cultural activities there.

—Kevin M. McGeough

What Do Historians and Archaeologists Mean by “Complexity”?

Historians and archaeologists use the term “complexity” or “complex societies” to refer to societies with forms of social differentiation that go beyond kinship principles. This is when the scale of social interaction surpasses the kin group, and therefore kin hierarchies are not extensive to the society as a whole. Thus, other levels of social difference and hierarchy that incorporate several kin groups are in place. The study of complexity in archaeology and history is comparative and has revolved around the emergence, trajectories, and functioning of complex societies in different times and places.

This approach is different from that used in other disciplines, such as sociology, management sciences, or computer sciences, in which academics see social complexity as part of wider patterns seen in the animal, plant, and inorganic physical worlds and model it for behavioral and decision research that aims to predict organizational trends.

The main body of theory that has guided the study of complex societies in archaeology is cultural evolution. According to this theory, trajectories of social complexity follow a succession in the form of societal types (from simple to complex): bands, tribes, chiefdoms, and states. For a long time, scholars have believed that the fundamental step toward societal complexity happened in chiefdoms, with the appearance of (1) social hierarchies based on ascribed status and (2) forms of social interdependence and specialization.

Ascribed status is when certain groups of people are thought to inherently possess certain qualities that make them superior, which results in institutionalized social differences. This is in contrast to systems of achieved status, when people, through performance, ascend socially. Systems of ascribed status become institutionalized because they are not contingent upon the

► HOW DO ARCHAEOLOGISTS SEE AND ANALYZE COMPLEXITY?

Archaeologists look at a variety of material evidence such as settlement and demographic patterns, public architecture, burials, household items, craft and food production, and consumption practices in order to understand social organization in the past. In this way, they are able to talk about how social differences were delineated in different societies, the nature of political authority and social hierarchy, and how and why these change in time and space.

—Andrea M. Cuéllar

achievements of people but instead build upon fundamental categories of social distinction that can come to reproduce themselves among and within several kinds of social groupings. For example, a social hierarchy based on a distinction between those who have more sacred essence than others could be reproduced on a smaller scale and differentiate between elite men and elite women as possessing differential degrees of sacredness. As other dimensions of social distinction are added, the system of social ranking can become nested and, indeed, very complex.

Social interdependence and specialization has to do with the degree to which individuals or kin groups rely on themselves for the fulfillment of all of their necessities. With specialization, individuals or kin groups depend on others for the acquisition of certain goods or services. These can include material items (ceramics, textiles) or ritual services, for example. It has been argued that specialization contributes to social status, as status is often expressed in the form of conspicuous material displays for which specialized craft production is required.

The evolutionary model has been criticized on both political and intellectual grounds. The political critique is founded on the argument that the model is ethnocentric, as it places the contemporary dominant Western type of sociopolitical organization (the state) on top. As a result, other forms of sociopolitical organization are

defined negatively in terms of what they lack when compared to the state, and thus they come to be seen as less complex, with a pejorative connotation. This in turn has opened fertile ground for several forms of domination.

The intellectual critique argues against the unilineal character of the model, as it has been observed that trajectories of social complexity are typically not a linear transition from one kind of societal type to the next. To the contrary, these trajectories are often full of reverses (when they pass from a superior stage to an inferior one), dead ends (societal types that did not develop into the next expected stage), or social orders that do not quite fit any of those defined in the model. The term “transegalitarian society” has been proposed to refer to complex social orders whereby social differentiation exists in the context of very weak political hierarchies. The term “heterarchical society” has also been proposed recently to account for cases in which multiple forms of political hierarchy coexist in the same society. More and more, the associations that were assumed to change hand in hand in trajectories of social complexity have proven to not hold together in the neat ways proposed by the model of cultural evolution. For example, the assumption that political complexity (a political hierarchy) should come along with economic complexity (specialization of production) cannot always be supported in the study of particular cases. Therefore, archaeologists are now focusing on understanding the great deal of variability among complex societies.

The Kintampo Complex of West Africa

Archaeologists have unearthed evidence for the transition from hunting and gathering to farming lifestyles around 2250 BCE in what are now Ghana and the Ivory Coast in West Africa. Although there is little evidence for the antecedents of these people and even less for their descendents, the people of what is called the Kintampo Complex had relatively standardized material culture. Every site has a variety of small tools that may include greenstone axes, quartz microliths, arrowheads, milling equipment, and stone rasps. Kintampo people made their own pottery, mostly large jars and bowls. Most sites have evidence for houses; only the stone foundations remain of what would have been rectangular daub huts. Some rock shelters were also used as domestic space. Kintampo sites also have evidence for the exploitation of wild and domestic plants and animals.

Based on the meager evidence we have of their precursors, Kintampo culture does reflect a substantial transformation in economic practices from their predecessors of the Late Stone Age (LSA). LSA sites in the region suggest that these people were hunters and gatherers who lived a relatively mobile lifestyle, seasonally returning to favorite sites including rock shelters. LSA sites have few luxury items and very little in the way of ceramics.

Based on this, it is believed that the Kintampo Complex reflects a movement toward a more sedentary lifeway. Rather than solely hunting and gathering, Kintampo people exploited a variety of food types including wild game, fish, domesticated sheep and/or goats, oil palms, and

WHAT IS A STONE RASP?

A particularly intriguing object, found in abundance at all Kintampo sites, is the stone rasp. These objects are usually made of soft stone (but there are some ceramic ones as well) and are scored very deeply all over the surface. Most rasps are roughly cylindrical. Archaeologists are not entirely sure what they were used for. They may have been used for decorating ceramics or for helping to shape clay pots. Given their resemblance to modern exfoliating devices, some have suggested that they were used to scrape dry skin off the body. Most likely they were used for food production, grating yams or mashing nuts and seeds.

—Kevin M. McGeough

incense tree seeds. It is possible that yam cultivation may have also occurred; however, there is no direct evidence for this.

These sedentary people also traded among each other. Exotic goods (objects that originated outside of the immediate area) are present at Kintampo sites in varying quantities and types. Some artifacts that could be interpreted as jewelry suggest that personal adornment was of interest. By about 750 BCE, the Kintampo Complex disappeared. Who replaced them is unclear; this particular period of West African history is not well understood.

The Egyptian Predynastic Period

From about 4000 BCE to about 3200 BCE, social complexity increased dramatically in Egypt. From 3200 to 3000 BCE, the first unified Egyptian state arose, but the origins of Egyptian civilization can be found in this earlier Predynastic period. According to Egyptian tradition, Egypt consisted of two distinct regions: the northern delta (Lower Egypt) and the southern floodplain (Upper Egypt). In the Predynastic period, these two regions remained distinct from one another

until sometime between 3500 and 3200 BCE, when Lower Egypt adopted (or was assimilated into) the cultural practices of Upper Egypt.

The Maadi Cultural Complex characterized Lower Egypt from about 4000–3500 BCE. This complex was named after the site of Maadi, located in a suburb of Cairo. Maadi was a village that extended over 0.8 mile (1.3 kilometers), although all of this space was never used at the same time. The houses at Maadi were semi-subterranean (pits); postholes and hearths have been found in association with these houses. The economy of Maadi included cereal cultivation, the exploitation of domesticated animals, and fishing. Evidence for donkey domestication has also been recovered at Maadi, indicating that this animal, which is still fundamental to rural Egyptian economic activity, has been in use for the past 6,000 years. Distinct local pottery forms were utilized by the people of Maadi as well as pottery imported from Syria-Palestine.

Contemporaneous with the Maadi complex was the Naqada I period (also known as the Amratian culture) in Upper Egypt. Naqada culture bears many similarities to the earlier Badarian culture, and scholars debate the relationship between these two cultural complexes. Most of the evidence for the Naqada I culture comes from the excavation of cemeteries. The dead were typically buried in simple oval pits with the bodies contracted, heads facing south and facing the west. The material culture found in these graves is considerably more diverse than that of the Badarian culture. Red-polished pottery continues from the Badarian period but develops into more numerous forms and designs. White-painted geometric designs on this red-polished pottery are especially noteworthy, as are images of riverine fauna. In this and other media, images of hunting and warfare are common. Funerary statuettes, disk-shaped maceheads, fish-tail lanceheads, and cosmetic palettes all appear at this time and are all forms that continue into Dynastic-era Egypt.

The Naqada II period (also known as the Gerzean) runs from about 3500–3200 BCE and is characterized by the expansion of Naqada culture as far south as Nubia and north into Lower Egypt. The site of Buto in Lower Egypt provides archaeological evidence of the transformation of northern society from the Maadi Cultural Com-

➤ PREDYNASTIC CHRONOLOGY

For Egyptologists, the Predynastic period refers to that time period prior to the rise of the Egyptian dynastic state. In the north of Egypt (Lower Egypt) it consists of the Neolithic period (ca. 5300–4000 BCE), which will not be discussed here, and the Maadi Cultural Complex (ca. 4000–3200 BCE). In southern Egypt (Upper Egypt) it consists of the Badarian period (ca. 4400–4000 BCE), the Amratian/Naqada I period (ca. 4000–3500 BCE), and the Gerzean/Naqada II period (ca. 3500–3200 BCE). The Naqada III period (ca. 3200–3000 BCE) is manifest in both Upper and Lower Egypt when the kings of Dynasty 0 ruled Egypt.

—Kevin M. McGeough

plex to Naqada, and by the end of the Naqada II period all of Egypt can be considered Naqada.

Naqada II material culture indicates considerably greater social complexity, with much more differentiated graves and grave goods. The most notable of these graves is Tomb 100 at Hierakonpolis, which has walls painted with images that are found on painted pottery vessels (such as boats and victorious warriors). Cosmetic palettes become less common but more elaborate, featuring elaborately sculpted art, and many of these palettes should be considered ceremonial or artistic as opposed to functional. Copper work and other specialized industries intensified in the Naqada II, concomitant with an increased interest in long-distance trade (especially with Syria-Palestine). Throughout Naqada II, society became increasingly hierarchical, and the roots for the later Egyptian state were established.

The Neolithic in Nubia

Although Nubia is located along the Nile Valley, the geography of Nubia is substantially different from that of Egypt. Egypt has long stretches of fertile floodplains that allowed the development of irrigation agriculture that could support a large population. Most of Nubia is broken up into significantly smaller patches of floodplain; only the Kerma floodplain was large enough to support a substantial agricultural regime prior to Roman period times. The Nile's course is broken up by cataracts, preventing easy transportation between what are otherwise close regions. However, there is significant evidence for trade among these Nubian communities. It is likely that each community interacted with the communities to the north and south along the Nile; this chain-like trade network allowed goods from northern Egypt and the interior of Africa to be traded, even with minimal long-distance transportation. Within this segmented environment, two regional subdivisions can be identified: Lower Nubia in the north (closest to Egypt) and Upper Nubia in the south.

The Neolithic is best understood in Lower Nubia, where mostly cemetery sites have been excavated. Archaeologists refer to the culture that appears here around 3500 BCE as A-Group culture, after their distinct ceramics (called A-Group Ware by an early excavator). The material culture of A-Group people was influenced by Egyptian material culture. Egyptian objects are found at A-Group sites, as are local variations of Egyptian objects such as stone cosmetic palettes that are distinctive to Predynastic Egypt. Nubian A-Group pottery is found at Egyptian sites in the south, demonstrating that the two cultures traded with one another.

A-Group culture was sedentary, with people living in permanent settlements. At the site of Afyeh, some houses built of stone were found, comprising a village of around seven acres (three hectares) in size. At other sites there is little evidence for architecture, suggesting that most buildings would have been made of materials that do not survive in the archaeological record. Estimates for the total population of A-Group culture vary from 5,000 people to 50,000 people at its height.

Although there is little direct evidence for economic activities, based on analysis of the cemeteries (and associated grave goods) it is likely that small-scale floodplain agriculture was incorporated into their subsistence regime. Given the ecological conditions of Lower Nubia, herding would have been a more important component of the lifestyle of the A-Group people. Given the variety and quality of material culture, especially pottery and stonework, it is likely that there were also craft specialists in Neolithic Nubia who spent most of their working time crafting specialty objects in exchange for the food produced by other members of their community.

A-Group cemeteries point to a marked social stratification as well. There is considerable difference in the wealth of grave goods and elaborateness of burials within A-Group cemeteries. This demonstrates that there was different access to wealth and different ranks within the community.

A-Group culture comes to an abrupt end during the period of the Egyptian First Dynasty. This was the result of Egyptian military incursions into the region, military incursions designed to gain control of the valuable trade resources available there. Local inhabitants are absent from the region until about 2400 BCE, when C-Group culture emerges in the region.

The Beginnings of the Chalcolithic Period in the Levant

The Chalcolithic period can be characterized as a time of great innovation and imagination, not only in the areas of art and architecture, but in cultural ecology, technology, and economic organization. During this time, people first settled

in the semiarid regions of the northern Negev and lower Jordan Valley. There is evidence that the climate may have been more humid in 4000 BCE than it is today, yet adaptation to these new and challenging ecological niches would still require ingenuity.

Farming remained the primary means of subsistence, and crops were much the same as those first domesticated during the Neolithic period. Barley, which can grow with as little as 200 mm (about 8 in.) of annual rainfall, was the main staple in the semiarid zones, and wheat was grown in the humid Mediterranean zone. A few new items, such as the olive, were added to the diet. In these more arid areas where dry farming was difficult, the Chalcolithic peoples implemented some of the earliest forms of water management systems. Analyses of phytoliths (silica skeletons from plants) conducted by Arlene Rosen indicate that at the small farming village of Shiqmim, floodwater farming and basin irrigation were employed in order to increase agricultural output. At the same time, animal husbandry began to evolve into a specialized form of economic activity, with an increased emphasis on the production of dairy goods (for example, cheese and clarified butter) and wool. This development is commonly known as the “secondary products revolution.” The faunal assemblages and large ceramic churns found at Chalcolithic sites (along with churns made of hide that do not survive) represent dairy production, and a vast number of spindle whorls indicate the spinning of wool.

This focus on the production of pastoral goods was part of a broader trend whereby a division of labor and craft specialization began to develop. Food production systems overall had become more efficient, allowing some people to engage in economic activities other than farming and herding. One of the key developments in the period—indeed, the one for which it is named—was the advent of metallurgy and the emergence of a local copper industry. The production of copper was a new technology that ultimately had a profound impact on society, both reflecting and producing changes in material existence, economic organization, and sociopolitical structure. From the Chalcolithic period, metals played a vital role in the economic his-

➤ EVIDENCE FOR SOCIAL HIERARCHIES IN THE SOUTHERN LEVANT

Several lines of evidence point to disparities in wealth during the Chalcolithic period. To begin, only a limited number of people seemed to have access to luxury goods such as ivory pendants, figurines, and metal scepters. The development of a prestige-oriented metal industry, in particular, seems to reflect the expression of power relations and the emergence of rising elites concerned with ways of legitimizing their authority. Investment in the development of metal technologies required sponsorship. It is possible that resources became concentrated in increasingly fewer hands as a result of control over large herds and/or agricultural surpluses by landholders, with luxury goods representing converted wealth.

The mortuary evidence from the Chalcolithic period also reflects a certain level of social hierarchy. Small children were still buried in the vicinity of the home, usually in the alleys between houses, often in jars. For the first time, adults were buried in clearly designated cemeteries outside of the village itself. The extensive cemetery at Shiqmim included a number of secondary burials involving small circular structures. It is possible that greater investment was made in some of these grave rings, though burial goods were generally modest. The most compelling evidence for social hierarchy during the Chalcolithic era has just begun to emerge over the past few decades with the discovery of a series of wealthy cave tombs. The Peqi'in burial cave included numerous individuals with a demographic distribution and grave goods that suggest it was used over a long period of time by an extended family or kin group with access to considerable wealth. Another noteworthy tomb has been found at Nahal Qanah, where archaeologists discovered a range of expensive items, including the earliest gold in the region.

—Jonathan Golden

tory of the region as an item of import and export, of production and consumption, of display and concealment, of celebration and solemn dedication. Its value was based on its rarity and aesthetic appeal as well as on its strength, for the emphasis on maceheads (for example, at Nahal

Mishmar) no doubt represents an association between metal and warfare.

There appear to have been two different copper industries during the Chalcolithic period. One industry focused on the production of tool-type items using pure copper and a technique of casting in open molds and hammering. The other used exotic, complex metals (copper with arsenic, antimony, and rarely, nickel) and the lost wax casting method to produce a range of more elaborate goods, many symbolically charged. Two primary sources for the “pure” copper are known in the southern Levant at Faynan and Timna, two different branches of the Wadi Arabah. Ores that probably derived from both these regions, along with crucibles, simple furnaces, and prills of raw copper, have been found at workshops in villages such as Abu Matar, and Shiqmim. Donkeys, which were first domesticated during the Chalcolithic era, were probably used to cart ore from the mines to the village workshops.

Information regarding the production of the complex metal castings has been elusive, though some new clues have recently emerged. A small piece of unworked copper with antimony from Bir es-Safadi has come to light, while crucibles and prills from Abu Matar indicate the processing of complex metals. The fact that the complex metals were used exclusively for the manufacture of prestige goods (such as scepters) suggests that this second industry involved attached specialization where production was sponsored by some elite group or political figure.

Another specialized craft was the production of groundstone and lithic goods. Working with hard stones such as basalt and limestone, craftspeople produced a variety of goods ranging from maceheads to elegantly sculpted stands commonly known as fenestrated incense burners, though their precise function remains uncertain. Studies in experimental archaeology suggest that flint tools, especially the adze, were probably used for working the basalt. Claire Epstein, conducting research in the Golan close to sources of raw material, has reported three circular basalt pieces that may represent bowls in the process of manufacture on site that were never completed. It is also feasible that at least some of

the basalt found at sites throughout the Chalcolithic landscape derived from the Golan, but petrographic analysis points to Transjordan as a source for artifacts found at the southern sites, and Epstein suggests that little of the local Golan basalt actually left the area. According to Yorke Rowan, product design became increasingly stylized, and overall quality improved with time. Specialization in flint tool production is evident in the fan-shaped scrapers as well as “proto-Canaanite blades,” both forms making use of a fine-grained material known as tabular flint. Tiny flakes and a blade core of very fine, translucent flint attest to the production of micro-blades, or micro-end scrapers, at Gilat.

Ceramic production also reached a level that would have required the skills of specialists. By the latter part of the Chalcolithic period, a class of pottery known as Cream Ware, notable for its fine quality and delicate design, emerged; one type from this group, the “V-shaped pot,” was made on the slow wheel, or tournette. Ceramic sculptures, best known from Gilat, also attest to an advanced level of craftsmanship.

The extent of exchange networks began to expand during the Chalcolithic period. Contact during the Chalcolithic era between the Golan sites and Syria-Lebanese sites such as Byblos, Ugarit, and the Amuq sites is seen largely through affinities in pottery styles. The discovery of obsidian at Gilat indicates the movement of materials from Anatolia as far south as the northern Negev. Overall, most trade items probably moved without a major overarching structure.

The Beginnings of Village Life in the Yemen (Southwest Arabia)

From around 7000 BCE, southwest Arabia enjoyed higher rainfall than today, supporting rich vegetation and creating lakes, even in parts of what today is desert. The region's inhabitants lived by hunting and gathering, moving to exploit seasonally available resources that on the coast included fish and shellfish. By or before 5000 BCE some groups also began herding cattle, sheep, and goats. Fourth-millennium evidence suggests that some communities made controlled use of bush fires to manage vegetation. Some groups also began limited cultivation, incorporating agriculture within their seasonal activities. Few traces of settlement survive from this period: the stone foundations of small groups of oval huts, grindstones for preparing plant foods, stone points used in hunting, and coastal shell middens.

It was not until the Bronze Age, from 3100 BCE, that farming communities began making pottery; a small amount of copper also came into use during the third millennium. By this time the monsoon winds had weakened, reducing rainfall. The highlands saw rapid population growth, perhaps partly due to migration from the increasingly arid lowlands. The main areas of settlement were in the mountains and the desert borderlands to their east, probably linked by the seasonal movements of pastoralists. Eastern Hadramawt was apparently more isolated from outside contact, as it remained without pottery until the first millennium BCE. The inhabit-

ants of coastal areas had slight contacts with parts of Africa across the Red Sea.

The main crops were wheat and barley and some pulses, derived ultimately from the Near East. It is possible that sorghum and millet, crops native to sub-Saharan Africa, were also grown, though there is no firm evidence of their early presence here. Villagers also continued to exploit wild plants such as grasses, fruit, and nuts and to hunt a little.

Settlements in the western highlands were generally situated on hilltops or plateaus. Those in Khawlan, the drier northeastern region, were generally small: one or several compounds composed of round houses arranged in a contiguous ring around a central open area. The houses had slightly sunken floors, and their roofs were supported by low walls of upright stone slabs and one or more interior posts. Simple dams were used to slow water running off the hills and capture silt for agriculture. However, pastoralism was the mainstay of the economy and involved raising sheep and goats.

Farther south in the highlands, the Dhamar plains received rainfall from two monsoons. Neolithic settlement in this area left little trace and may have been limited; in contrast, the area saw substantial Bronze Age occupation. Settlements here were larger, especially during the second millennium BCE, sometimes reaching 14.8 acres (6 hectares), and some were walled. There were also small satellite settlements. The houses were rectangular, often with several rooms; although some were similar in their construction to those farther north, others had walls of coursed masonry, some several yards high. In some settlements such as Karraib, the houses were scattered; in others, they were grouped in blocks separated by streets. This was the case at Hammat al-Qa, which also had several internal walls subdividing the settlement. In the northeast side of the perimeter wall were two gateways flanked by orthostats (upright stone slabs); orthostats were also used for the house doorways. Several houses had a walled open space at one end, and many had a square or rectangular annex. A nearby hilltop served as an obsidian-working site, using raw material collected in the valley below.

➤ DESERT TOMBS AND MEGALITHS

Throughout the desert borderlands and in the eastern part of the western mountains, communities built substantial chamber tombs. These were built mainly during the third and early second millennia, though some continued in use for much longer. Built of stone blocks, those in Hadramawt had a small central chamber roofed by stone slabs or corbelling, generally used for a single burial. Farther northwest the tombs were taller, resembling a tower, and had a doorway so that they could be used for many successive burials. Smaller tombs, small cairns, platforms, and other stone features were often associated. Carved stelae were sometimes built into the outer wall of the Hadramawt tombs. These often depict a warrior with a dagger. Bronze daggers and other small objects were recovered from some graves, though most have been plundered. These tombs form part of a wider tradition of funerary architecture among pastoralists over much of Arabia.

In the coastal region, massive lines or clusters of huge stone pillars were erected, such as at Hajar al-Ghaymah. In the disturbed group at al-Midaman on the Red Sea coast excavations revealed burials, usually of an infant, beneath many of the pillars; one covered a cache of daggers and other copper objects, dated around 2400–1800 BCE. Erecting the pillars here represented a huge investment of time and effort. They were massive, some as long as 7.7 yards (7 meters), and were made of granite and basalt, stones not available within a 31.1-mile (50-kilometer) radius of the site.

—Jane R. McIntosh

The available agricultural land was maximized by constructing terraced fields with stone retaining walls on the slopes of the hills bordering the plateau and high valleys; the earliest surviving trace of such a terrace, at Sedd adh-Dhra'ah, is dated to around 3800 BCE. The valley floor provided pasture for domestic animals: sheep, goats, and some cattle. Threshing floors, of which traces survive from the late third millennium onward, were constructed in suitable windy locations among the fields.

In desert borderlands east of the mountains including the western Hadramawt, the way of life was similar, although there may have been some specialized pastoralism. Settlement was concentrated around the oases and wadis through which flowed seasonal torrents from the mountains. In addition to cereals and pulses, date palms may have been grown in this lowland region. Various methods of water management had already been developed. Check-dams in gullies or streams, which slow the flow of spate water, are of considerable antiquity: one example at Wadi Sana, stratified below a later working floor, dates back to around 4500 BCE. In Wadi Idim the remains of *shruj* (low walls or lines of cobbles that diverted sheet wash on to agricultural plots) were found that may have been created in the Bronze Age. Calculations based on the depth of silt deposits indicate that dam irrigation was in use by the third millennium BCE, for example, in the Marib oasis. Canals and revetments that channel slope wash or upstream water onto terraced fields may also date back to the Bronze Age. In the eastern Hadramawt, herding was the main economic base, supplemented by a little agriculture where suitable conditions prevailed.

Traces of small villages have been found in the region. Sh'ib Munayder on the southern Jol plateau was a linear settlement dating back to the mid-second millennium. Its round houses had foundations of stone uprights supporting stone lower walls. Occasionally there was a small structure attached to the outside, presumably an animal pen. Upslope of the houses were large cairns probably containing burials and smaller chambered cairns perhaps used for storage. At Shabwa, mud-brick houses and pottery dating back to around 2000 BCE were found beneath the later town.

The people of the coastal regions continued to exploit marine resources, as is witnessed by the vast shell midden at Sihi and other midden sites, bones from which show that animal husbandry was also important. From the earlier part of the Bronze Age there are slight traces of substantial settlements based on marine fishing and irrigation farming, using simple dams and irrigation channels as in the eastern lowlands. Small

soundings show that the lower levels of the deeply stratified site of Sabr probably date back to the late third millennium.

Southwest Arabia saw major changes in the later second millennium. Interregional exchange and communications and external contacts greatly increased: for example, obsidian from Dhamar now became the main material for stone tools in many parts of southwestern Arabia. Copper objects, previously extremely rare, now came into common use in coastal regions. The development of the lowland wadis east of the mountains began to take off, laying the foundations for the later incense-trading kingdoms of the region. Settlement declined in the arid northern highlands during the second millennium, but elsewhere settlements increased in size, some eventually housing as many as 500 people. New settlements were founded in the late second millennium such as Hajar ibn Humayd in Qataban and Hawagir in Dhamar, the latter a massive (30.89–37.1 acres, or 12.5–15 hectares) unwallled town, unusual in being situated on the valley floor perhaps to take full advantage of the large expanse of cultivable land or to bestride an increasingly important trade route. The excavated upper levels at Sabr, dated to 1400–900/800 BCE, reveal a substantial town. Houses in its center were rectangular mud-brick structures, some with an internal courtyard, while those on the edge of the town were small circular huts with post walls; these differences may reflect social distinctions. Part of the settlement was devoted to industrial activities including metal production, and there was also a central complex of larger buildings, probably public buildings, including a possible temple with storerooms.

The Neolithic in China

One of the fastest-changing fields of archaeological study is the Chinese Neolithic. Experts' understanding of this period in Chinese prehistory has shifted constantly since the first excavations in the 1920s. Unexpected finds are the norm in this field of study in which thousands of sites all across China contribute to the ever-changing picture. In general, the Chinese Neolithic can be characterized as a series of regional cultures, each emerging as a sedentary agricultural-based society with specific adaptations to the particular regional environment. Given the wide variety of types of Neolithic finds and the environmentally diverse regions in which they are found, it is not clear when it makes sense to think of these Neolithic cultures as Chinese per se. Arguably, the most interesting question to emerge from the study of Neolithic China is how these sites relate to the origins of the Chinese state. Most of the cultures are named after their type site (the first site at which the culture was identified). However, this leads to numerous problems, as different scholars see different connections between sites. A culture for one scholar may merely be a city for another scholar. What follows is a brief summary of the major regional Neolithic cultures that have been identified so far.

Yangshao (5000/ 4500–3000/2500 BCE)

The best known of the Neolithic cultures, the Yangshao culture, is located in the middle of the Yellow River valley. More than 1,000 sites have been identified as Yangshao. The people who lived at these sites were millet farmers, although there is some evidence of social stratification and craft specialization. Perhaps the clearest evidence of social stratification is the tomb at Puyang belonging to the so-called Puyang Shaman. The tomb featured a man buried with a clam-shell effigy of a dragon on the left and a tiger on the right as well as various elaborate grave goods.

Yangshao pottery is very distinctive; it is dark red and painted with brown or black designs. The designs vary from abstract geometric figures to more elaborate schemes, such as mask

and fish combinations. Specialists subdivide the Yangshao period into various subphases based on the stylistic changes in this pottery.

The site of Banpo is particularly important, so much so that some scholars argue for a separate Banpo culture lasting from 4800 to 3600 BCE. This seems to be a relatively egalitarian community; all of the sunken-floor huts were roughly the same size except for one much larger building. Animal enclosures were present, attesting to the importance of domesticated animals for the Banpo subsistence economy. The whole site was surrounded by a circular ditch, probably to help prevent flooding but possibly for defensive purposes as well.

Majiayao (3500–1500 BCE)

The Majiayao represents a western extension of the Yangshao culture. Majiayao sites are easily identified by their distinctive painted pottery, decorated mostly with circles or anthropomorphic figures.

Dawenkou (5000–3000 BCE)

Located on the lakes and shores of the Shandong Highlands, the Dawenkou culture was highly stratified. Most of what is known about the Dawenkou culture comes from the investigation of its burials because most of the excavated sites are cemeteries. Burials follow a fairly standard

Painted ceramic jar, Majiayao/Yangshao culture, China, about 2000 BCE. (Christie's Images/Corbis)

pattern: one large relatively shallow pit is dug followed by a significantly deeper pit in the center of the original. The body of the deceased is interred in the center pit (inside a wooden coffin), and grave goods are spread around the shallow pit. The variety of grave goods is noteworthy; dozens of stone, bone, and jade objects are found. Wheel-made pottery is also found within the graves. The amount and quality of goods varies, indicating a society where individuals had different amounts of wealth and power from one another.

Majiabang (5000–3500 BCE) and Hemudu (5000–3300 BCE)

These two cultures are found along the Yangzi River in Jiangsu and northern Zhejiang. Both cultures engaged in rice agriculture as their primary form of subsistence, supplementing it with the cultivation of various freshwater plants. They also fished and raised dogs, water buffalo, and pigs. What is different about the two cultures is their pottery: Majiabang pottery is brown, and Hemudu pottery is black. Some scholars differentiate these cultures from the later Songze (4000–3000 BCE) and Qinglian'gang (4000–3600 BCE) that are located on the coast. The

Qinglian'gang culture is noteworthy for its early skilled jade craftsmanship.

Daxi (5000–3000 BCE)

Also located along the Yangzi River (in the Yangzijiang Valley), the Daxi culture is one of the first in China to erect walls around its villages. The villages were also home to what appear to be large communal storage facilities, suggesting long-term subsistence planning. Daxi material culture is distinctive, with its highly polished stones and slate sickles.

Hongshan (3000–2500 BCE)

The Hongshan people of Inner Mongolia and Liaoning were millet farmers and cattle and sheep breeders. Elaborately carved jades belonging to this culture have been retrieved from cist graves at Hongshan sites. Many of these jades are carved in the shapes of animals. Loops in the jades suggest that they may have been hung from clothing. Two temples may also have been identified at Dongshanzui and Niuheiliang. Both temples consist of stone platforms. They are set apart from other structures by installations of terra-cotta cylinders near groups of small female figurines.

Dapenkeng (5000–2500 BCE)

Dapenkeng is located in southern China, and the pottery differs from other Chinese pottery in that it is very coarse, with only simple cord-impressed decorations. This was a coastal culture, dependent on fishing and the exploitation of a variety of water plants. Hunting also seems to have played an important role in Dapenkeng culture, even after sedentary agricultural practices were established.

Liangzhu (3300–2200 BCE)

Located on the east coast of China (in Zhejiang, Jiangsu, and Shanghai), the Liangzhu culture created some of the most beautiful artifacts of Neolithic China. The wheel-thrown black ceramics are likely precursors of the fine black Longshan pottery. Many of these artifacts have been retrieved from funerary contexts. One of the

➤ CHANGING CONCEPTIONS OF THE CHINESE NEOLITHIC

Conceptions of the Neolithic period in China have drastically changed over the past century of research. Ancient historical accounts suggested that Chinese civilization began in the Yellow River valley (not surprisingly since these ancient writers lived in the Yellow River valley). This idea, however, was not seriously challenged until the 1920s, when Johan Gunnar Andersson discovered Yangshao and declared that many of the cultural elements found there had originated in western Asia. In the 1930s, Fu Sinian suggested a different understanding: Chinese civilization emerged in two distinct regions, in the interior and along the coast. In the 1960s the majority view shifted once again, suggesting that agriculture emerged first in the central plain and then spread outward. Archaeology then slowed down in China (due to the Cultural Revolution). When it reemerged, scholars now conceived of the Chinese Neolithic as consisting of separate regional interacting spheres, the approach presented above. Given how quickly ideas about the Chinese Neolithic seem to change, one wonders how much longer it will be until this conception is outdated.

—Kevin M. McGeough

most elaborate burial sites is Tomb Number 3 from Sidun in Jiangsu. There, more than 200 ritual objects (including weapons) were recovered. *Cong* (white jade cylinders) were found in the tomb and bear the image of an anthropomorphic deity with feathers for hair and an animal-like face. Small round jade disks with holes in the center (called *bi*) were also recovered. Without a doubt, finds such as this demonstrate that Liangzhu society was far more stratified than earlier Neolithic cultures in China. This is in evidence at the intervillage level as well. The site of Liangzhu, for example, actually consists of more than 12 separate villages of varying size. Power is normally assumed to be related to size (although this is not always a safe assumption), and it is assumed that there was a hierarchical power structure that connected this cluster of settlements. It is estimated that there were hundreds of these clusters of sites.

Longshan (2500–1700 BCE)

Spread along the Yellow River basin, the Longshan culture seems to have had connections to previous Yellow River cultures as well as some of the coastal cultures (especially the Liangzhu). Subsistence was mixed, with heavy reliance on agriculture as well as domesticated animals. With hundreds of sites, Longshan culture was highly stratified and possibly prone to conflict. Many sites have defensive fortifications (the earliest are found in Henan). These fortifications (or *hang tu*) were built by ramming earth between wooden slats and then ramming each layer firmer and firmer.

The stratification of Longshan society is most apparent in its burials. At the site of Taosi, for example, several thousand graves have been identified. Of those that have been excavated, about 6 were large (with abundant high-quality grave goods), 80 were medium-sized (with fewer grave goods, mostly of lesser quality), and about 600 were small (with only minimal grave goods). Archaeologists infer from this that there were a few leaders of great importance, a small amount of upper-class individuals, and a large poorer base.

Longshan material culture is varied, probably coinciding with burgeoning ideas about the value of personal (as opposed to public) wealth. Ceramics are wheel-made; the most elaborate is very fine, thin, black polished pottery. Interesting finds are deer scapula that have been purposefully burnt and subsequently cracked; these may be precursors of a later divinatory tradition.

From Fishing to Farming—The Introduction of Rice to Korea

The introduction of rice into the diet of ancient Koreans brought about profound changes and marks the end of the Korean Neolithic Age. It was around 2000 BCE that rice was introduced into Korea from China, although the exact mechanisms of the introduction are unknown. Was rice brought as part of a larger migration of people to the region? Or were rice agricultural practices learned by local peoples from encounters with Chinese rice farmers? The scholarly consensus now favors the latter explanation regarding the 500 years following the first introduction of rice as a gradual period of transition.

Before rice agriculture, ancient Korean culture is often referred to as Chulmun culture. This is a problematic term, since it better refers to the ceramics typical of Korea at this time. Archaeologists call these ceramics “comb-ware” after the incised geometric decorations. The most distinctive form of vessel is the wide-mouthed conical pot. Also typical of Chulmun material culture is the predominance of flaked stone tools (stone tools made by chipping or knapping the stone) as opposed to stone tools manufactured using grinding techniques. Archaeologists are still attempting to refine the dating for this culture, but generally scholars see it as beginning sometime between 6000 and 5000 BCE and ending around 2000 BCE.

Chulmun sites are very small; at most, 10 to 20 houses are occupied at any given time. These houses are semisubterranean and are large enough to accommodate a nuclear family. Sites are often found clustered together, suggesting some sort of larger tribal organization beyond the level of the individual village. Generally these sites are located along the seacoast or on river terraces. Given the location of these villages and the types of material culture in evidence, it is assumed that fishing was one of the primary means of subsistence for the Chulmun. Hunting wild game and collecting wild plants supplemented this diet. Carbonized remains of cereals (especially

millet) have been found in late Chulmun sites, suggesting that toward the end of the Chulmun period, ancient Koreans were also reliant on small-scale horticultural production. These cereals supplemented their hunting and gathering lifestyle.

From about 2000 BCE until 1500 BCE, scholars see a gradual transition from the Chulmun culture to the Mumun culture, culminating in the introduction of rice around 1500 BCE. Over the course of 500 years, gradual changes in the material culture and settlement patterns of the ancient Koreans provide evidence for a profound cultural transformation. Mumun also refers to a specific type of pottery, a plain coarse ware that is very different from the preceding Chulmun pottery. The Neolithic is understood to end around 2000 BCE, and the Bronze Age begins, lasting until 300 BCE (even though bronze does not appear in Korea until 1000 BCE).

Concomitant with the introduction of rice are a number of other changes to Korean society, although it is impossible, given the present state of knowledge, to determine whether rice agriculture led to these changes, came along with these changes, or was facilitated by these changes. Pottery changes dramatically, and flaked stone tools are replaced by ground stone tools. House types and sizes start to vary dramatically, with very small and very large houses within the same site. The goods found within homes also varies; every house has farming equipment like sickles, but not every house has polished stone daggers, indicating some level of social differentiation. Social differentiation is also evident in burials. Grave goods vary in value and quantity, and the graves themselves vary in scale. Megaliths and dolmens are a feature of the Mumun landscape, indicating that these burials are part of a larger symbolic system of social differentiation. Trade in precious stone is somewhat evident, although there is only minimal evidence for any long-distance exchange. The stone daggers and stone maceheads that now appear may suggest that warfare became more common in the Bronze Age. More directly related to the introduction of rice agriculture is a shift in settlement strategy. Bronze Age villages are found inland and are more evenly spread out. No doubt this was to facilitate agriculture. Since the type of rice grown

in this period is grown in a paddy, rivers would have been diverted to flood the fields. Fishing, it is assumed, has become less of an important subsistence practice, possibly due in part to a decrease in fishing stocks because of overfishing during the Neolithic.

Jomon—Hunters, Gatherers, and Potters

The Middle Jomon period began around 3600 BCE and ended sometime between 2500 and 2000 BCE. Climate during the Middle Jomon is characterized by being warmer and more humid than today. Vegetation was characterized by the expansion of deciduous and evergreen broad-leaved forests.

Settlement size and population density were at their peak during the Middle Jomon period. In northeastern and central Japan, large sites (sites with more than ten pithouses) are common. It has been estimated that the population in the archipelago during the Middle Jomon period was approximately 260,000.

A broad range of resources were used for subsistence during the Jomon periods. Nitrogen and carbon isotope data from human skeletal remains indicate that most of the foods eaten were plants. Hunting of deer and boar was done primarily in the winter. In the spring and summer, grasses, roots, and shoots could be collected and eaten. Acorns, buckeyes, horse chestnuts, and fruits were collected in the autumn, processed, and then eaten. Complex harpoons and fish-

Jomon culture earthenware bowl. The Jomon, thought to be the earliest inhabitants of Japan, are named after their coiled clay pottery. (Sakamoto Photo Research Laboratory/Corbis)

hooks found in shell middens suggest the exploitation of marine mammals and fish. Faunal analyses of several midden sites indicated that a variety of freshwater and marine fish were also eaten. Large shell middens, such as Kasori in Chiba prefecture, point to the exploitation of shellfish during the Middle, Late, and Final Jomon periods.

There is floral evidence that the Jomon cultivated several plants, although they were not a primary source of food. Bottle gourds (*Lagenaria siceraria*), beans (*Vigna angularis*), and mulberry are a few of the plants cultivated by Jomon hunter-gatherers. DNA evidence also suggests that chestnuts may have been cultivated at Sannai Maruyama and elsewhere during the Middle Jomon period.

The Middle Jomon period is also characterized by a variety of elaborately decorated pottery styles. While there are a variety of regional variants, most archaeologists see six major style

zones dating during the Middle Jomon period. In addition to the characteristic cord marking, the various pottery styles are decorated with raised clay reliefs and sculpted rims. Deep jars are the most common vessel form, but shallow bowls were also made. The Umataka, or flame, style of pottery from present-day Niigata prefecture is considered to be one of the most elaborate pottery styles.

The Late Jomon period coincides with the start of deteriorating climatic conditions. Depending on the locality and the evidence used, Neoglacial conditions started as early as 2500 BCE based on evidence from the Kanto region or possibly as late as 2000 BCE based on evidence from the Tohoku region.

There is a marked decline in settlement size in the Late Jomon. While surveys in northeastern Japan indicate that the number of settlements and burial sites increased from the Middle Jomon period through the Late Jomon period, the number of pit dwellings at each site decreased. For example, in Aomori prefecture there are 620 sites, 46 of which are settlement sites that date to the Middle Jomon period. These 46 settlement sites contain just over 600 pithouses. For the Late Jomon period there are 1,518 sites, but only 56 of them are settlement sites. Just over 400 pithouses were excavated at these Late Jomon settlements.

Despite the decline in settlement size during the Late Jomon period, social complexity and ritual activity increased. Stone circles, while seen in earlier periods, are common during the Late and Final Jomon periods of northeastern Japan. Two types of stone circles have been excavated. The first type, exemplified by the site of Komakino in Aomori prefecture, consists of large circular rings of stone. The second group of stone circles consists of groups of small paved stone clusters. The sundials at Oyu in Akita prefecture characterize this second form. Excavations at paved stone circles in Hokkaido indicate that they were used as markers for burials.

➤ KOMAKINO SITE

The Komakino site consists of three concentric stone circles. The outer ring has a diameter of 115 feet (35 meters), the next one a diameter of 95 feet (29 meters), and the inner ring a diameter of 8 feet (2.5 meters). Approximately 2,400 boulders were used in its construction. Unlike the stone circles in Europe, most of the stones used at Komakino lie flat on the ground and only a few are set upright. Pit burials were found on the east side of the outermost stone circle, while jar burials were found between the outer and first inner ring. Small paved stone features are associated with the outer two stone circles.

Settling Down—New Social Organization in Late Archaic North America

During the Late Archaic period in North America, major changes in social organization took place as prehistoric peoples settled down into sedentary or semisedentary lifeway patterns. While populations varied in their internal organization and relations with other groups, prior to the shift in social organization they are generally thought to have been egalitarian, meaning that they lacked institutionalized differences in status and power that would affect access to

► SOCIAL ORGANIZATION ON THE SOUTHERN NORTHWEST COAST

By the Late Archaic (3,000–1,500 years before the present) the people of the southern Northwest Coast of North America lived in permanent villages and had a complex social organization that included long-distance trade and exchange, cooperative resource extraction, and the construction of large architectural structures. Sites such as Ozette, which contains the remains of several large cedar plank houses, 6,000 woven or twisted plant fiber objects, and evidence of trade goods, attest to the complexity of the social organization along the southern Northwest Coast. Furthermore, the distribution of household goods within archaeological sites clearly indicates variation in the social standing of individual nuclear families. Likewise, evidence from La Push, Sooes, and Neah Bay indicate that economic orientation, social standing, and intercommunity relationships were fairly extensive throughout the region by this time. The emergence of larger regional polities began at this time, and there is evidence that these regional polities warred with each other over access to key resources.

—Peter N. Jones

key resources. It is important to note, however, that generalizations about social organization gloss significant regional differences and inter-regional variations. In general, mating networks are thought to have shifted from open to closed, unequal divisions within local groups developed and became solidified, complex trade and exchange networks formed, and populations coalesced in the formation of villages and regional polities.

Evidence from the Northwest Coast indicates that the social organization of the region was highly diverse during the Late Archaic period, as some regions appear to have been highly organized while others were more egalitarian. For example, evidence from the Marpole site argues that peoples of the Fraser River mouth were egalitarian in organization. Very few burials have been found, and those that have been studied show no major differences in the mode

of disposal of individuals or in the accumulation of wealth. However, some evidence indicates that head deformation and tooth abrasion took place, possibly indicating some form of mild social ranking. By 400 BCE–400 CE evidence indicates that settlements increased in size and that people within the same village had different levels of social status. During this period some burials become rich in dentalia, shale, and shell beads, while others lack any forms of burial goods. Likewise, there are individuals with deformed skulls, while others lack this feature, possibly indicating a difference in ascribed status from infancy.

Farther south along the coast of Oregon, evidence indicates that people were organized in local kin-based groups associated with particular localities. These groups controlled camp and village house sites along with specific resource exploitation areas. Inter-marriage was most likely an important mechanism of regional interaction, and evidence indicates that exchange networks linked these people with groups on the other side of the Cascade Mountains and into the Plateau and Great Basin regions.

Evidence from the Plateau indicates that it was not until the Late Archaic period that social organization in the region reached its apex. Disparities in house sizes and variations in the amount, quality, and exotic character of burial furniture on both the middle Fraser and middle Columbia reached their greatest extent during this epoch, evidencing growing social inequality. Social organization reached a level of complexity that involved the cooperative management of resources including anadromous fish along the river bottoms and upland resources. Furthermore, rock art and large cemeteries began to appear, marking the identity of different bands of people at this time and indicating that the landscape was being divided up into various social territories.

In the southern Great Basin, the Late Archaic brought about a great change in social organization among the prehistoric peoples of the region. Prior to the Late Archaic, people lived in small groups practicing a cyclical lifeway pattern based on the availability of seasonal resources. However, around 1,700–1,200 years before the present the people of the region adopted horti-

culture, and evidence indicates that social organization changed greatly as a result. During this period, people lived in relatively small villages in semisubterranean pithouses with masonry and adobe surface structures. Ceramics were also adopted, some of which exhibit evidence of time-intensive decoration, indicating that some individuals were able to spend time on nonutilitarian activities.

In eastern North America there is evidence for the division between the cultural manifestations that were a result of various social organizational changes taking place in the Late Archaic period. For example, evidence from Hopewell indicates that the social organization of the Northeast and the Midwest at this time became highly complex. While long-distance trade and exchange is evidenced for the area during earlier times, it was not until Hopewell that this system reached its peak. Gulf Coast conch shells are found in Michigan and Wisconsin, shark teeth are found in mounds in Illinois, copper from Lake Superior is found in the far South, and obsidian from the Rocky Mountains is found in Illinois and Ohio. Similarly, large mounds as well as what appear to have been regional exchange centers were constructed during this period.

In the Southeast, the complex shell and earthen mound centers dating to 5,000–4,000 years ago reflect the actions of many band-sized groups that were bound together into new social formations by collective ceremonial activity. Evidence indicates that communities consisted of 30 to 50 individuals in several households and that some individuals within the community held a higher social status than others. Likewise, there is scant evidence for communal feasting, ritual, and other behavior associated with the large earthen mounds found at this time. By 2,000–1,500 years ago, however, there is evidence of hierarchically organized societies in some parts of the Southeast.

Horticulture and Complexity in North America

A sign of developing social complexity in North America is the transition from reliance on wild animals and plants to the purposeful cultivation of these wild species. This type of subsistence, in between hunting/gathering and agriculture, is called horticulture or animal husbandry. This change in subsistence strategy has greater implications than dietary. It points to new forms of sociopolitical organization, new types of settlement patterns, and possibly new senses of ownership and occupational roles.

Horticulture requires people to live a more sedentary existence since they have to be near where their crops grow for much of the year. The exploitation of plant species in this manner also requires that people intervene in the plant's natural environment; otherwise the plants will be fully harvested in a very rapid amount of time. This type of intervention can be very simple and much like what you do in your own garden

➤ HORTICULTURE OR AGRICULTURE— HOW TO TELL ARCHAEOLOGICALLY

Seeds, pits, and other plant remains preserve remarkably well archaeologically in many different environments. Archaeologists use relatively simple practices called flotation techniques to retrieve these very small botanical remains from the soil of sites. When a soil sample is immersed in water, material such as seeds and pits float to the surface. Paleobotanists can easily collect this material to gain direct evidence about what plants were available at a particular site. Other materials can provide indirect evidence; for example, insect body parts can tell us what plant life was present if we know what types of plants those insects fed on.

With this material it is often possible to determine whether wild or domesticated plant crops were present at a site. Generally, wild plants become domesticated through selective harvesting and planting. For example, wheat with a brittle rachis (central axis) breaks quite easily, so wind or the movement of animals can scatter the seeds easily, thus making these particular plants difficult to harvest for seed. On the other hand, wheat with a tough rachis will not scatter easily. Humans can harvest this and then replant it, and the genetic traits that gave the wheat the tough rachis are perpetuated in the human-managed crop. After years of this, differences can become apparent in the seeds themselves. So, in the initial stages of this process, it is very difficult to distinguish domestic plants from wild plants.

—Kevin M. McGeough

today: watering, planting, weeding, and landscaping. In the eastern woodland region of North America, during the period between 1000 BCE and 300 CE indigenous crops (such as sunflowers) were encouraged, as were imported plants (such as gourds and squash).

An interesting question about this period's horticulture in the eastern woodlands is why this transition took place. The first scholars to tackle this question generally assumed that stresses of various sorts played the most important roles. Overpopulation could have forced the people of the eastern woodlands to consider alternative forms of resource management. This

would have involved exploiting food resources that could be stored over longer periods of time or were more easily traded with other groups or between families. Conflict with neighboring peoples could have limited the mobility of eastern woodlands people, forcing them to make do in a smaller area less suitable for hunting and gathering. However, there is limited evidence for these stresses. More recent scholarship has suggested that this transition was a gradual and casual one. People slowly started encouraging certain plants to grow and started to think of certain regions as their own.

The Development of Sedentary Society in Mesoamerica

In the period between 4000 BCE and 1000 BCE, Mesoamerican society became an increasingly more sedentary society. At the beginning of this period, agriculture (especially maize agriculture) provided only a small component of dietary needs. By the end of the period, much of Mesoamerica was heavily reliant on agriculture and firmly situated in sedentary villages.

Beginning at around 8000 BCE, Archaic society was predominant in Mesoamerica. Archaic society is found throughout the Americas; it is identifiable by distinct types of stone tools and

by subsistence practices that incorporate hunting and gathering and some small-scale horticulture. The transition from Archaic society in Mesoamerica has been well studied in the arid Tehuacán Valley. From about 3825 BCE until about 2600 BCE, most of the sites in this region were temporary campsites. People would move seasonally in order to be closer to their food sources. Some permanent sites have been identified, and reliance on wild animals and plants seems to have lessened. There is not as much information for the period from 2600 BCE to 1600 BCE during which sedentary villages became the norm, as did reliance on domesticated plants. During this period the first ceramics appear, often taken as a hallmark of sedentary agricultural subsistence practices since ceramics can be awkward to transport. After 1600 BCE, there were small villages (of perhaps 100–300 people) that depended almost completely on agriculture for their dietary needs.

The Archaic period was over in Mesoamerica by about 2000 BCE. Mesoamerican scholars use a bewildering array of terms to refer to the period after the Archaic period. The two most common are the Initial Formative (which is how it will be referred to here) and the Early Preclassic. The two most distinct changes in Mesoamerican life during the Initial Formative are the development of complex society and the development of regional differentiation. Complex societies begin to emerge throughout Mesoamerica at this time, developing along different lines in different environments.

Large settlements began to appear in Mazatan around 1800, peaking around 1500 BCE and declining by about 1350 BCE. Called the Mokaya (“people of the corn”), the settlements were made up of large central villages (which could support up to 1,000 people) and smaller hamlets. The Mokaya subsisted mainly on crops but also traded obsidian, salt, and possibly cacao. The best-known site is Paso de la Amada, which demonstrates significant social differentiation. An elite residence here was substantially larger than other houses, indicating a disparity in wealth between upper and lower classes. Also of note is the ball court.

Villages in the Oaxaca Valley were not quite as large; the largest held up to 600 people. How-

ever, the same two-tiered settlement hierarchy (large villages and small hamlets) is evident. Rectangular wattle and daub huts are grouped in clusters in the villages. These clusters are often associated with pits, probably used for longer-term food storage. While the huts were about the same size, the amount and quantity of furnishings varied considerably. Likewise, burials exhibit similar patterns of wealth and/or status differentiation, further suggesting that society in the Oaxaca Valley had become stratified by this time.

Sites located near Lake Texcoco, in the Basin of Mexico, also demonstrate a two-tiered hierarchy. This region’s ceramics are very noteworthy, coming into use around 1500 BCE. A cemetery excavated at the site of Tlatilco revealed numerous elaborate ceramic figurines. Each figurine is unique, depicting individuals in a variety of costumes and poses as well as creatures with three eyes or men with two heads.

The Rise of Sedentism in North America

Considerable debate has focused on the nature of demographic change in North America, centering largely on when sedentism arose and for what reasons. Although it is now fairly well accepted that sedentary processes were unique in each region of North America, general characteristics of the process have been identified: an increase in population size and/or pressure, a certain level of technological development, and the large-scale availability of resources. Within each region these processes, along with regionally idiosyncratic factors, came together to give rise to sedentary lifeway patterns in North America.

On the Northwest Coast, for example, evidence indicates that the site of Namu was a sedentary village dependent on a salmon economy

SEDENTISM ON THE SOUTHERN PLATEAU

Sedentism is generally thought to occur when population levels reach a certain density and when technologies are developed that permit exploitation of resources to support such population levels. In the southern Plateau region of North America, sedentism was initially thought to have arisen fairly late in prehistory. Archaeological excavations at Rufus Woods Lake on the upper Columbia River, however, have pushed back the date for sedentism on the Columbia Plateau to at least 3000 BCE. Traditional explicators such as intensified salmon fishing, root collection, or the development of storage facilities have not been able to account for early settlements on the upper Columbia River. Site 45-OK-11, with a series of housepit communities dating between 3200 and 2000 BCE, evidences year-round occupation with perhaps as many as four to five dwellings in use at any one time. A broadly based subsistence economy focused on hunting large game and collecting freshwater shellfish, supplemented by fishing and root collection, provided enough resources for sedentism to occur.

—Peter N. Jones

by about 5000 BCE. Furthermore, the evidence from Namu predates by several millennia the first substantial evidence for population expansion or social differentiation in the region, characteristics generally associated with a sedentary population. Because of the abundant salmon

Site layout of the Poverty Point earthworks in Louisiana.
(Jon Gibson/Louisiana Division of Archaeology)

resources, however, people were able to practice sedentary lifeway patterns on the Northwest Coast several thousand years before other regions in North America.

The availability of subsistence resources was not necessarily the driving force in peoples' decisions to adopt a sedentary lifeway in all regions. In southern Arizona, for example, evidence indicates that the earliest farmers in the Hohokam region were not significantly more sedentary than their Archaic era predecessors. In this region population expansion and pressure appear to have been driving forces in the development of sedentary lifeways rather than an overall abundance of subsistence resources.

In the Lower Mississippi River region, on the other hand, people were able to maintain a fisher-hunter-gatherer subsistence economy as they also adopted a sedentary lifeway. For example, evidence indicates that Middle Archaic (5400–3100 BCE) people were not fully sedentary, but by the time the Poverty Point earthwork was built sometime around 1700 BCE, these people had become sedentary. In this region, unlike in the Southwest, the colossal earthwork, the explosion of material culture, complex trade and exchange networks, and the swift accommodations to growing population appear to have been both cause and consequence of the rise of sedentism.

A consequence of the rise of sedentism in North America was a shift in subsistence modes from hunting and gathering to a mixed economy utilizing domesticated plants. Along with the shift in subsistence mode was a subsequent change in prehistoric North American people's skeletal size. For example, evidence from the Georgia coast indicates that when prehistoric peoples became sedentary, a significant postcranial skeletal size reduction occurred. This indicates that as prehistoric peoples shifted to a sedentary lifeway that relied on a mixed economy, there was a decrease in the level of musculoskeletal stress. Along with a decrease in stress came a change in lithic technology and hafting techniques. Because people were no longer moving around the landscape as much, lithic tools became more valuable as access to lithic procurement sites became less available.

The Valdivia Culture of Ecuador

Excavations at the site of Valdivia in the 1950s transformed scholarly understandings of ancient Ecuador. What was unearthed there were the remains of an ancient village that had been inhabited during the Early Formative period (3300–1500 BCE), a village that showed signs of stratified social roles, complex economic activities, and elaborate pottery. Until these excavations, scholars had assumed that complex civilization did not emerge in this region until centuries later. As further excavations in Ecuador have demonstrated (especially at the site of Real Alto), this village at the mouth of the Valdivia River valley was not an isolated phenomenon but instead was one village in part of a larger cultural horizon, stretching along the coast of Ecuador. Archaeologists call this the Valdivia culture, named after the type of site (the first site excavated that can be associated with that culture).

➤ SCHOLARLY CONTROVERSIES—JAPANESE VOYAGES TO ECUADOR?

Some aspects of the pottery of the Valdivia culture bear a striking resemblance to that of the Jomon people of Japan, so much so in fact that a scholarly minority (led by Betty Meggers, Clifford Evans, and Emilio Estrada) has argued that pottery was introduced to the Americas from Japan around 3600 BCE. Pottery shards found in western Kyushu (in present-day Japan) have stylistic similarities with Valdivian sherds and possibly common production techniques. Individual sections of the pots, especially bases and rims, also display similarities. However, when whole forms (as opposed to the broken pieces called sherds) are examined, the similarities are less apparent. Further weakening this interesting theory is the fact that the earliest phases of Valdivian pottery show no similarities to Jomon styles. Scholars who believe that there were Transpacific connections in 4000 BCE–300 CE argue that the similarities that are apparent do not reflect a direct borrowing but instead reflect a shared circumpacific style that is associated with ancient maritime cultures.

—Kevin M. McGeough

Donald Lathrap has argued that the Valdivia culture emerged as part of a larger population movement out of the Amazon Basin. The predecessors of the Valdivia engaged in subsistence practices adapted to the tropical forests. An alternative theory holds that early Valdivia culture was more influenced by ancient Japanese travelers to South America, although this theory has largely been abandoned. At Valdivia and other Valdivian sites, a shift toward more sedentary subsistence practices occurred. Permanent houses were built (out of wattle and daub), ceremonial centers were used, and towns were planned along a general U-shape. Now living in permanent houses, the people of Valdivia participated in a mixed economy, exploiting a number of different food sources. Shell middens and shell fish-hooks attest to the importance of seafood in the diet. Hunting and gathering also took place, probably practices continued from the Valdivian origins in the tropical forest. Horticulture was

also practiced, with maize, beans, and root crops being the most important food sources; cotton may also have been exploited. Not every type of economic practice is attested at every site, suggesting that intersite trade and craft specialization connected the various villages.

The ceramics of Valdivia are particularly noteworthy and play an important role in archaeological reconstructions of Valdivian chronology. Most of the pottery is made of fine sand, gray in color (although there are some red vessels), and is made by coiling. Valdivia pottery has a variety of designs and decorations; the most common form is the wide-mouth jar. Valdivia figurines are also quite noteworthy. Made of stone and ceramics, the earliest seem to be humans, although it is impossible to determine which sex is represented. Later figurines are almost entirely nude females. The function of these figurines is unclear.

The Growth of Complexity in the Andes during the Late Archaic Period

From 3000 to 1800 BCE during what archaeologists usually call the Late Archaic period, Andean civilizations went through a number of transformations. These transformations were not uniform throughout the region, but some general patterns can be noted. Many of these transformations played an important role in the development of complex state-level civilization in the Andes, culminating in the Inca. Two constants are present throughout the Andean Late Archaic: cotton becomes the textile of choice, and no pottery is used at all.

Throughout the Andes, most sites were relatively small. In some areas, hunting and gathering remained the dominant mode of subsistence. However, at a number of sites, people began living in permanent villages in permanent houses. These villagers came to rely more heavily on domesticated plants (as opposed to wild gathered plants). There is no evidence for one staple crop throughout the Andes at this time; the Late Archaic remains a transitional period where the villagers are better understood to be engaging in horticulture as opposed to large-scale agriculture.

Domesticated animals also play a more important role. The remains of *cuy* (guinea pigs) are found at many sites. These creatures were eaten, and while they would not have provided much food, they would have been a good supplementary source of protein. More important was the more intensive exploitation of camelids (llamas). Wild llamas had been hunted in the past; while they continued to be a good source of meat, they also provided wool and acted as

Kotosh, Late Archaic site in present-day Peru. (Gustavo Madico)

pack animals. During the Late Archaic period, ancient Andeans became better at herd management, making deliberate decisions about when to kill (and consume) certain members of the herd, which animals should be selectively bred (and when), and how to provide fodder for these animals.

Hints of burgeoning social stratification and centralized decision-making also appear in the archaeological record during the Late Archaic period. Three sites in particular demonstrate this, although it is presumed that these trends may be found elsewhere in the Andes in further explorations. At the site of Kotosh, two mounds estimated at 8.7 yards (8 meters) high were in use for more than 1,000 years. Most noteworthy are the many superimposed temples (when one was destroyed or fell out of use, a new one was built directly atop the remains of the previous). The temple layouts are relatively distinct and are referred to by archaeologists as the Kotosh religious tradition. The site of Huaricato, which has not been extensively explored, has ceremonial hearths similar to those at Kotosh. A similar set of superimposed temples was also found at La Galgada. Here in front of the main mound was a circular plaza, walled, with a staircase leading down into the interior.

One area of the Andes that seems to develop along different lines is the Norte Chico region.

► THE PARANA-PAMPEAN TRADITION

Another South American cultural group that seems to transition from hunting and gathering lifestyles to more settled subsistence practices at some point between 1500 BCE and 500 CE is referred to as the Parana-Pampean tradition. The tradition is named after the region in which they lived, which includes parts of Patagonia and some of the lowland stretches of the Andes. “Tradition” is a term that archaeologists use for long-lasting cultural groups (this group seems to survive from 7000 BCE to 1500 CE). Known mostly from their stone tools (and their distinctive triangular stemmed projectile points), what had once been a hunting and gathering culture gradually developed into a settled culture dependent on domesticated plants for their subsistence. The appearance of pottery around 500 CE marks the end of what scholars refer to as the Early Parana-Pampean Tradition.

—Kevin M. McGeough

Here, the first elements of what will later become Inca society are manifest: the sunken plaza and the Staff God. The sunken plaza is similar to that found in La Galgada in the Norte Chico region; more than forty plazas dating to the Late Archaic period have been so far identified, suggesting that the inhabitants of La Galgada modeled their plaza after those found in Norte Chico. The Staff God, who later is understood by the Inca as a creator deity, appears on two carved gourds found in the region. The Norte Chico region also seems to have the largest and most stratified communities. The site of Aspero, especially, is significantly more complex than other Andean sites dating to this period. There was a heavy reliance on domesticated crops, cotton being especially important. Substantial platform mounds have also been identified.

Caral

The Peruvian site known as Caral has been dated to the early third millennium BCE and was one of 20 or more urban centers in that region that together may constitute the earliest complex society in the Western Hemisphere. As the Great Pyramids of Giza rose along the fringes of the Nile floodplain, corps of builders erected stone platform mounds in the arid river valleys that descend from the Andes to the Pacific Ocean along Peru’s north-central coast. While Caral bears some of the traits common among other early complex societies of the world, it may have taken a strikingly different path to civilization. Evidence gathered from human and plant remains at Caral suggests that its inhabitants did not produce the surpluses of staple crops often assumed to be the necessary prerequisite for the emergence of complex societies. Instead, residents of Caral appear to have practiced subsistence agriculture that centered around the cultivation of cotton and gourds, which in all likelihood they bartered for fish and shellfish from coastal residents who in turn needed these products for the production of nets and floats. This intricate symbiotic relationship between harvesters of the sea and harvesters of the land as well as the apparent absence of surpluses of staple crops challenges the commonly accepted model explaining how humans organized themselves into increasingly complex forms of society.

Caral is located 124 miles (200 kilometers) north of Lima in the Supe River valley, 14 miles (23 kilometers) inland from the Pacific Ocean. At more than 270 acres, it is one of the largest archaeological sites in the Andes. Although it was first recorded in 1905, significant studies of Caral have been conducted only since the mid-1990s. The site’s central zone is dominated by six monumental platform mounds, the largest of which, the so-called Piramide Mayor, measures 524 feet (160 meters) by 492 feet (150 meters) and is 59 feet (18 meters) high. At its base is located a large circular plaza, sunken about 3 feet (1 meter) into the ground and connected to the top of the platform via a stairway 32 feet (10 meters) wide. Sunken circular plazas such as the three at Caral are one of the identifying characteristics of many Preceramic sites in the Supe

River valley as well as the valleys of nearby rivers. Also discovered at Caral are numerous smaller platform mounds as well as extensive residential complexes. Some of these residences bear indications of having been home to Caral's elite. Built of dressed stone sheathed in painted plaster, in some cases they are located on top of or connected to platform mounds. More humble abodes were made of wood, cane, and mud, a building technique still in use among residents of the Supe Valley. Radiocarbon dates taken from reed bags used to transport rubble to the site indicate that Caral's platform mounds date to at least 2627 BCE. In total, there are 24 known Preceramic sites in the northern coastal region of Peru, many the contemporaries of Caral and each bearing the common features of large platform mounds, circular ceremonial plazas, residential architecture, and evidence of irrigation agriculture.

Scholars disagree about the sequence of events that led to the emergence of complex societies in Peru at the outset of the third millennium BCE. There are two main theories. The first, popularized in the mid-1970s by Michael Moseley, asserts that the initial steps toward civilization were taken by fishing societies along the central and northern coastal region of Peru. According to this theory, fishing created the demand for specific cultivated crops, such as cotton for nets, that eventually led to the development of large-scale irrigation agriculture along the inland river valleys. The second theory, expounded mainly by archaeologists working at Caral, sees the initiation of civilization in the Andes as originating in the river valleys, with irrigation agriculture then spreading to the coast. In either case, what is clear is that the emergence of complex society in ancient Peru was the result of a unique cooperation between people living in very different communities and occupying very different professions.

Human populations living along Peru's littoral have been taking advantage of the riches of coastal fisheries since as early as 12,000 years ago. However, in order to support growing populations, fishing communities grew increasingly dependent on certain plant products that were not readily available along the coast. In particular, plant fibers were needed for nets, fishing line,

and clothing, and gourds were needed for net floats and other containers. The archaeological record of Preceramic sites along Peru's north-central coast suggest that when coastal peoples began to domesticate plants, they did not choose the kind of staple crops selected by residents of the world's other early complex societies. Instead, they chose to cultivate crops that would supply them with the resources they needed to maximize fishing production: cotton and gourd. The debate among scholars is currently over where the transition from more simple forms of organization to true complex society first took place (along the coast or along inland river floodplains) and why (as a result of the coastal fishing industry or inland irrigation agriculture).

Whichever the case, evidence from sites such as Caral offers further support to the idea that economic cooperation between these two regions and two occupations was a pivotal factor in the transition to complex society. Archaeologists have uncovered human refuse and waste remains at Caral that indicate residents' primary source of protein derived from fish and shellfish, not land animals. The large quantities of sardine and anchovy bones that have been discovered in human coprolites and refuse support this conclusion. In addition to the remains of marine life, archaeologists have discovered large amounts of cotton seeds, fibers, and textiles at Caral. It seems likely therefore that Caral's residents grew crops such as cotton, which they then bartered for the fish and shellfish that were the basis of their diet.

The significance of Caral to our understanding of world history is great. First, the discovery of a complex society in Peru dating to the early third millennium BCE pushes back the earliest dates for the emergence of complex society in the Western Hemisphere by nearly 1,000 years. Prior to this discovery it was believed that complex societies had evolved at this time only in Africa and Eurasia. Second, north-coastal Peru is a unique case study for the evolution of complex societies, one that differs from the commonly accepted pattern followed by societies in the so-called Old World. Caral and the other Preceramic sites of northern coastal Peru stand to offer scholars valuable new insights into why and how humans made the transition from

more simple to more complex forms of social organization.

■ Introduction: Mining and Resource Acquisition

The acquisition of resources for production is a fundamental component of economic life. From the period 4000–1000 BCE, the acquisition of these resources on a large scale is well attested. Resource-poor regions like Egypt and Mesopotamia organized long-distance trade and/or mining expeditions to acquire mineral and forest resources from locations well away from major centers. Resource-rich locations such as Elam (in Iran) and Nubia profited from their trade with other regions yet also experienced invasions by groups who wanted direct control of these materials.

Smaller-scale mining operations are identifiable throughout the world in the period 4000–1000 BCE. Most of the evidence for these mining or quarrying operations comes in the form of archaeological remains of those activities. Remnants of mining tools or landscapes altered by mining are the best sources of evidence for these activities. Often the evidence for ancient mining has been obscured by the passage of time. Many aboveground deposits that would have been available to the ancients were mined away completely long ago, thus eradicating any traces of those activities. Indirect evidence for mining also takes the form of the artifacts that were produced from raw resources that were mined. Any metal or stone tool is indirect evidence of this type of resource acquisition since the materials the tools were made of were mined or quarried at some point. What follows is a discussion of some of the better-known examples of

ancient mining and resource acquisition activities that occurred between 4000 and 1000 BCE.

—Kevin M. McGeough

Stone Quarrying in Egypt and the Near East

Stone was one of the most important resources for the ancient Egyptians. Modern visitors to Egypt marvel at the monumental stone art and architecture that has endured to the present. The Egyptians were highly skilled stonemasons and incorporated this material into much of their construction. The Mesopotamians were also quite skilled at stonework even though their stone had to be imported from Iran (across the Zagros Mountains). In both Egypt and Iran, quarrying techniques were similar; what differed was the organization of the quarrying enterprises.

In Egypt, most large-scale mining enterprises were commissioned by the king and/or the government. Mining teams were led by military expeditions, staffed with a large bureaucracy to oversee the quarrying. The miners themselves were conscripted laborers, slaves, and foreign soldiers captured during military campaigns. For Mesopotamia the situation is less clear, since the actual mining took place outside of the king's direct sphere of influence. Small-scale quarrying, however, was done by individuals according to their own skills and whims.

The main techniques for removing large amounts of stone from quarries in 4000 BCE–

300 CE were to detach large blocks from cliffs, remove boulders from dried river valleys, and carve trenches around large blocks of stone. Trenching was most effective for large blocks: since large blocks would have been too heavy to lift very high, it was easier to pound out trenches around the block, allowing it to be rolled out of the deposit. An unfinished obelisk (a large free-standing pillar) that was abandoned by Egyptian miners at a granite quarry near Aswan has allowed modern archaeologists to reconstruct these practices in detail. First, the miners stripped off the weathered layers of the stone: the imperfect parts of the stone that would not have made for quality artistic materials. Next, trenches were excavated around the stone, roughing out the shape of an obelisk. The trenches were quite large; in this particular case, more than 50 workers could have been working at one time. Measurement marks left by overseers, dictating where cuts in the stone were to be made, are still evident. Eventually the obelisk would have been undercut, allowing the obelisk to be rolled out of the trench.

Holes for rectangular wedges found in the granite quarry had initially led archaeologists to believe that wet pieces of wood were wedged into the stone and used to leverage out the stone. Experimental archaeology has shown that this technique would not have worked since the wood was not strong enough. These rectangular holes were probably left by later miners, who were using iron tools sometime after 1000 BCE. In the Bronze Age, the tools were modest. Axes and pointed picks were used for roughing out the stone. Chisels were hammered with mallets for finer work. With only these small tools available, the ability to quarry large quantities of stone was dependent on the ability to marshal large labor forces.

The bulk of the large stone resources quarried by the Egyptians came from the deserts and cliffs to the west and east of the Nile Valley and in the Sinai Desert. These quarries were in marginal locations away from major settlements, too far from the Nile to allow for permanent settlements. Settlements designed for the miners were set up in some locations and varied in size. At Umm el-Sawwant, the location of a gypsum quarry, a large settlement of at least 250 stone

➤ DEIR EL-MEDINA—THE WORKERS' VILLAGE

Deir el-Medina is an ancient Egyptian village that was home to the artisans who built the temples and tombs ordered by the pharaohs and other dignitaries in the Valley of the Kings. About 100 stonecutters, artisans, and civil servants lived here during the New Kingdom period. (Erich Lessing/Art Resource, NY)

One of the strategies that the Egyptian state used to organize mass labor was to establish villages devoted to one particular job or craft. Deir el-Medina is one of these villages that has been excavated by archaeologists. Located near the Valley of the Kings and the Valley of the Queens, this village contained the homes of the builders of the tombs of the New Kingdom pharaohs and their families. Anybody involved in the creation of the tombs lived in this village, including the builders of the tombs and the artists who carved and painted the walls. The families of these workers lived in the villages, and so did individuals who worked to support the tomb craftsmen, building their homes, manufacturing their tools, and providing them with food.

—Kevin M. McGeough

structures was built. There, workers not only quarried stone but also engaged in secondary stone production, producing flint tools and stone vessels.

The transport of stone once it had been quarried was a significant undertaking. The Egyptians invested a great deal of resources in constructing roads to facilitate the movement of stone across the sandy deserts to the Nile Valley. These roads were built of paved or dry stone. Transporting stone across the Zagros Mountains

to Mesopotamia was not as difficult since there was no sinking sand to deal with.

Metals

Metal exchanged hands in the ancient world in the form of both raw material and finished product. In general, it appears that the ancient Near East was mineral poor, but perhaps future systematic survey and scientific investigation of ancient mines will fill the substantial gaps in our knowledge of ancient sources of ore. Much of our knowledge of metalwork comes from hoards or tombs. In the ancient Near East, as in modern times, people valued copper and iron for utilitarian items and gold or silver for decorative objects. Tin was highly prized, for it was used in producing tin-bronze, a versatile copper alloy utilized from the Early Bronze through the Iron Age.

Gold and silver may be found in scattered deposits throughout the Near East. Gold was relatively plentiful in Egypt's eastern deserts and Nubia, although evidence for the mines is scarce. A few artifacts originally identified as pure gold, including pieces from the Ur cemetery, have since been shown to be electrum, which contains both gold and silver. Native silver is rare. More frequently, it must be extracted from lead ore by cupellation, a heating process that oxidizes lead to separate the silver. Sources of lead and silver are known from Asia Minor, especially in the region of the Taurus Mountains. Gold and silver were exploited for the first time during the fourth millennium BCE.

It appears that copper was the first metal to be exploited in antiquity. Weathered copper ap-

pears as an attractive blue color that may have attracted Neolithic people to collect and use the material for ornamental purposes but who soon discovered utilitarian applications for it. Beads, pins, and awls of native copper are known as early as the eighth millennium BCE in Anatolia and the mid-seventh to mid-fifth millennia BCE in Iran, regions where the metal was most accessible. By the fourth millennium BCE, copper technology had spread across the Near East. Most known mines only suggest small-scale production of utilitarian items, but large-scale operations were conducted in several locations. Arsenical copper was the common alloying agent used to produce the harder and more durable arsenic-bronze objects found throughout the Near East from the fourth through third millennia. This alloying agent may have been traded over great distances. Mines in the Wadi Arabah (in Israel and Jordan) at Feinan and Timnah that were exploited heavily for copper from the Chalcolithic through Early Bronze Age do not contain arsenic. There are, however, rich copper deposits in Iran, especially at the Talmessi mine, that carry a high arsenic content. In the early third millennium BCE, the regions around the Persian Gulf (Oman in particular) supplied copper to Mesopotamia. Feinan and Timnah ceased production in the Middle and Late Bronze Ages when the island of Cyprus, known as Alashiya in ancient texts, rose to prominence as a major supplier of copper for the eastern Mediterranean.

Tin appeared in the latter half of the Early Bronze Age and eventually replaced arsenical copper as the primary choice of alloying agent. The reasons for this shift remain uncertain since arsenic-bronze is comparable to tin-bronze in most characteristics. The sources of tin are equally unclear. Despite the discovery of mines and surviving tin deposits in the Taurus Mountains, the certainty of this potential source has been challenged, partially on textual grounds. Early-second-millennium BCE texts discovered at the Anatolian site of the Karum Kanesh reveal a trade network that brought tin into Anatolia from the south to trade for silver and gold. This suggests the lack of tin sources from within Anatolia. Tin sources may be found in Afghanistan, where deposits of alluvial gold and tin (in the form of cassiterite) are known.

Although the origin of ironworking technology is obscure, iron rose to prominence following the end of the Late Bronze Age. Tin-bronze, however, continued to be used especially for complex cast objects such as figurines. Iron served primarily for utilitarian objects, tools, and weapons. The appearance of iron should not be viewed as the arrival of a superior metal. Wrought iron is softer than tin-bronze. In addition, iron is more difficult to produce than bronze, and iron-casting technology did not arrive until the nineteenth century CE. Iron can become harder and more durable if alloyed with carbon (forming steel), quenched, and properly tempered, but there is limited evidence for the common application of this process before the eleventh century BCE. Some suggest that the rise of iron was the result of disruption of the tin supply and trade. Unlike tin deposits, iron ore is relatively plentiful in most regions. Given the scarcity and expense of tin, metalsmiths may have welcomed new technology to work the more abundant resource. Alternatively, the shift toward iron might have been an ecological choice. Less heat is needed to work iron than copper or bronze, and thus less fuel is required. Given that much of the Near East is poor in wood, the benefit of adopting iron is clear.

➤ PRECOINAGE MONEY

Some products in ancient marketplaces were exchanged for standardized quantities of precious metal. Coinage was not known until the seventh century BCE, when it appeared for the first time in ancient Lydia. Prior to this period, the monetary system was based on pieces of metal weighed on a scale balance against a standardized system of weights. Different systems of weights existed throughout the ancient Near East. Simple stone weights were commonly used, although more elaborate weights have been discovered. A large cache of animal-shaped (zoomorphic) weights were discovered on the Late Bronze Age Uluburun shipwreck. The metal to be traded for could be molded into regular shapes and sizes, but often the desired weight was simply cut from a larger fragment or even from recycled pieces of broken jewelry. Silver was more common than gold, and small bags of cut-up silver pieces (*hacksilver*), likely intended for use in trade, have been recovered in archaeological sites.

—Adam Aja

Forestry (Silviculture)

Neither Egypt nor Mesopotamia had large sources of timber, yet both societies were heavily reliant on wood and wood products. Wood was necessary for construction as well as for wooden products such as furniture, tools, boxes, and so on. Wood was also needed for use as fuel in the production of pottery and metals. Tremendous amounts of wood are required to produce charcoal, an essential component for establishing the high heats necessary in ancient heavy industries.

Locally available wood in Mesopotamia and Egypt may have been sufficient for small craft projects and utilitarian tools. However, for luxury objects such as furniture and any sort of construction project, the people of these regions had to look elsewhere for supplies. Wood, especially ebony, came from the south, from what is now called the Sudan. The most important source of wood for Egypt was Lebanon, renowned for its cedar and within close proximity to the Mediterranean for easy sea transport. This

» WOODWORKING IN EGYPT

The ancient Egyptians were quite adept woodworkers even though wood was in short supply in the Nile Valley. They used adzes and chisels for small projects and both pull saws and short saws for cutting larger section of wood. The Egyptians sanded the wood and were aware that wood is strongest along the grain, and they utilized it accordingly. Daily life scenes from the walls of the Tomb of Rekhmire depict Egyptian woodworkers in action. And numerous wooden pieces of art have survived from ancient times. In other locations wood rots relatively quickly, so the wooden finds from Egypt are very important. One of the most noteworthy is a statue dating from the Old Kingdom called the Sheikh el-Beled. The statue is a very lifelike rendering of a portly, elderly official; the Egyptian workers who excavated the statue claimed that it was the spitting image of the local sheikh and thus named it after him.

—Kevin M. McGeough

was not as convenient for the Mesopotamians, who did not have a Mediterranean port. For them, wood came from the Zagros Mountains or from Anatolia, shipped downriver as large logs.

The appetite for wood in Egypt was insatiable. The Palermo Stone records that the Fourth Dynasty king Snefru had 40 ships filled with cedar imported from Byblos, the large port on the Lebanese coast. A text from the reign of King Thutmose III of the Eighteenth Dynasty records that a shipyard imported over 2,000 feet of wood from Lebanon over an eight-month period. Wood used in architecture tends not to survive archaeologically. Archaeologists can estimate the amount of wood used in projects by studying the sockets left in stone walls, where the wood has decomposed. A relatively safe estimate is that 2,000 trees would have been needed for a 150-room palace, composed mostly of stone. Even given the huge amounts of wood harvested from Lebanon, it was not until Roman times that deforestation became a significant problem in that region.

Reliefs from the Egyptian Temple of Karnak preserve information about the actual harvest-

ing of trees. One man would cut the base of a tree, while a team of men would hold ropes supporting the tree to control its fall. The tree would then be sawn into lumber and seasoned to reduce its moisture content. The most common method of seasoning the wood was to stack the lumber in such a way as to allow air to circulate throughout the pile, drying out the wood.

Copper Mining in Southeast Asia

Copper is essential for the manufacture of bronze (which is an alloy usually composed of tin and copper). With the advent of metallurgy in Southeast Asia, sources of copper began to be exploited throughout the region. One mine, located at Phu Lon on the southern bank of the Mekong River, has been excavated by the Thailand Archaeometallurgy Project. Radiocarbon dates of charcoal found at the site suggest that the mine was used as early as 1700 BCE and continued well into the first millennium. It is thought that the site was used seasonally; miners would come to the area for a brief period, spending just enough time extracting the copper ore and processing it into an easily transportable form before moving away again. There is no evidence that this site would have been permanently occupied.

The mine itself is better thought of as a mining complex, since both extraction and processing took place within the vicinity. Copper sulfide ore is present, running in deep veins through the limestone at the site. Ancient miners created numerous shafts as they removed small blocks of copper ore, probably through heating the rock and alternating between smashing and exerting pressure against the limestone. The small

chunks of copper ore were further processed nearby in small workstations at what the excavators called the pottery flat. There, the ancient miners used small cobbles of rock (which they left behind) to further crush the copper ore-limestone that had been removed from the shafts in order to fully separate the copper (and thus not waste effort transporting undesirable limestone). Ceramic crucibles were found, indicating that some of the copper was reduced to a molten state at the site. The remains of molds also suggest that perhaps some casting took place at the site as well. There is no evidence that the copper ore was alloyed with tin here, thus there is no proof of bronze manufacture. The location of the mine near the Mekong River allowed easy transportation of the processed goods.

Jade and Precious Stones in Mesoamerica

Jade, or more properly jadeite, was the most important mineral for ancient Mesoamericans. Its value to them was the equivalent of diamonds in modern Western society. Because jade was so precious, great effort was spent in its extraction, shaping, and design. Mesoamerican jade comes in three different colors: blue-green, green, and purple. Blue-green jade was a favorite of the Olmec people, while green jade was desired by the Maya. Purple was not used anciently. The chemical structure of jade, $\text{NaAl}(\text{Si}_2\text{O}_6)$, makes it an extremely hard mineral, 6.5–7 on a scale of 10 (diamonds are rated 10).

Jade-bearing rocks were extracted from the Motagua River basin in Guatemala. River cobbles could be collected from the river itself, but larger pieces were found in seams along the mountain-

Ceremonial adze, representing the Olmec "God I" with his typical flaming eyebrows. Olmec art was a major influence on early Maya art, green jadeite (1200–800 BCE). (Erich Lessing/Art Resource, NY)

ous sides of the river basin. Locally, this basin is known as the Sierra de las Minas, or the mountain range of the mines, a reference to its high mineral content. Once the jade cobbles or boulders were found, they were tested for quality before more effort was put into them. Jade is a hard stone, which means that the only effective way of shaping it was using jade hammer stones to break apart the jade cobbles. This was done with direct percussion, flaking off a corner of the jade cobble to see its quality. Poor-quality pieces were discarded, and high-quality pieces were brought to camp for further processing.

Obsidian was another important stone. Obsidian-bearing strata were followed into hills and deep into the ground, as necessary. This stone

► SCHOLARLY CONTROVERSY—THE ORIGINS OF BRONZE IN SOUTHEAST ASIA

A controversial issue that has yet to be settled by scholars of Southeast Asia is where the technology for the manufacturing of bronze in Thailand and Vietnam came from. Charles Higham has argued that there are two major hypotheses, neither of which can be settled given the present state of evidence. The first is that the technology was gradually acquired from China sometime between 1700 and 1500 BCE. This is consistent with bronze finds from sites such as Dong Dau and Go Mun, where bronze artifacts of utilitarian and decorative functions have been recovered. The second hypothesis is that an independent bronze-making tradition developed in Thailand. This hypothesis was favored after the initial discovery of bronzes from Non Nok Tha and Ban Chiang were dated to about 3500 BCE. Recent reevaluation of these dates suggests that they should be lowered to about 1500 BCE, which is more consistent with the first hypothesis. At present, there is no way to settle the issue one way or the other about the origins of Thai metallurgy, but continued excavation may reveal the answer.

—Kevin M. McGeough

comes in different colors depending on the precise chemical makeup of the volcanic matrix in which the glass formed. Most obsidian is black, but some sources are gray, black and gray mixed, and green. Green obsidian, found in the Pachuca area of central Mexico, was particularly prized for its color. Obsidian was mined by exposing a strata of volcanic glass and chipping off large chunks via percussion blows with hammer stones. The hammer stones were usually quartzite cobbles slightly larger than a human hand. Obsidian fractures in concentric concoidal rings as the force from the blow expands outward from the point of impact. Skilled flint knappers can control the direction of the blow so that the energy flows through the obsidian block and shears it off at a predetermined point. The

chunks of obsidian removed are called tool blanks. The high-quality tool blanks were then brought to camp for further work.

Obsidian processing occurred through a combination of percussion and pressure flaking. Percussion flaking utilizes hammer stones to directly impact on the surface of the obsidian. The transferred energy pulls off flakes. Pressure flaking involved positioning the point of a tool, such as an antler tine, on an edge of the obsidian tool blank and then pushing the tool so that the energy released moved through the obsidian and pushed off a flake. Flakes removed via percussion have different attributes than those removed via pressure. Percussion flaking is generally used to remove large quantities of undesired mass from the obsidian, while pressure flaking is for fine work.

Jade was also percussion flaked. Flint knappers used the same basic techniques on both minerals to create a mass of the proper size. However, jade required a more labor-intensive approach than obsidian. Once the jade was the proper size, it was generally worked with abrasive materials. Jade dust could be wrapped in a cord and rubbed against the surface to smooth out irregularities. Holes were drilled into the jade using hard stone or wood with abrasive dust. Then the entire surface was smoothed and polished for hours on end.

■ Introduction: Ancient Workshops and the Organization of Production

Given the large amounts of specialized production that must have gone on in the earliest urban states, there is surprisingly little archaeological evidence for craft workshops. Archaeologists have recovered huge quantities of goods from the cities of Egypt, Mesopotamia, Greece, India, and China that would have required specialized training to produce yet have found relatively few workshops. In fact, recent research has shown that sites that were once thought to have preserved workshops were in fact misunderstood by their excavators. For example, the city of Ugarit, located on the coast, was once assumed to have separate industrial zones within the city, with subsections devoted to specific industries. Recent reanalysis of the site has shown that in fact there is no evidence for this kind of urban planning and that there is only minimal evidence that any production activities took place within the city.

The absence of heavy industries within cities is not surprising, in reality. The heavy industries common to the ancient world (brick making, pottery manufacture, and metallurgy) require huge amounts of heat and/or space. The unpleasant environment created by kilns, the difficulties of transporting fuel (wood and dung), and the dangers posed by fires would have made it worthwhile to situate these industries outside of the cities proper. This may explain why so few of these workshops have been uncovered, since archaeologists have tended to concentrate on the excavation of urban areas, only surveying rural regions (of course, there are noteworthy exceptions). It should be noted that the occasional heavy industry workshop has been found within an urban center. At least six kilns have been excavated at Mohenjo-daro in Pakistan, and a bronze foundry has been identified within the ancient city of Erlitou in China.

Archaeologists more often find smaller-scale workshops designed for light industrial production (stone, jewelry, shell crafts) within urban centers. These industries do not require large spaces, nor do they require the large amounts of

heat typical of other industries. They also do not require large storage space for the tools or raw materials. These workshops are usually quite small. The largest workshops are found in Egypt, although these are not really large workshops but rather a series of small workshops, reduplicated over and over in a modular fashion. So unlike modern factories, where production can occur on a large scale, ancient production would have been slow and limited. The Egyptian modular workshops would not have been able to produce substantial quantities of products, although they would have facilitated apprentice-style training and the sharing of equipment.

Apprenticeship training was the norm for the early urban states. There were no formal craft schools, at least none that we know of. Regional standards did develop, and techniques and styles were often relatively standard over long distances, attesting to significant contact between craft specialists throughout regions and hinting at some sort of internal organization of these workers. Some of this organization could have come from royal or temple patronage, since the state, especially in Egypt and China, did seem to sponsor some craft activities. More important in the spread of production techniques and styles were the networks that existed between the different cities and villages within the ancient states.

The networks that connected ancient cities and villages through the exchange of specialized goods played a role in cultivating specialized craft workshops. In the Indus Valley and Mesopotamia, there is significant evidence for regional specialization in certain industries. For example, the Mesopotamian city of Isin was, for a time, a center of leather production, and the city of Chanhudaro was an important center for bead production. In contrast, larger centers do not demonstrate evidence for this kind of specialization, and in general the percentage of space devoted to specialist activities is significantly higher in smaller villages as opposed to larger centers. These larger centers may have relied on facilitating the exchange of specialist

THE EGYPTIAN “SATIRE OF THE TRADES”

One of the most enjoyable Egyptian texts is the *Satire of the Trades*, which dates to the Middle Kingdom. In this document, a father lectures his son on the hardships of the various trades. About coppersmiths, the father says that their skin is like a crocodiles and their stench is worse than fish eggs. Stonemasons and jewelers, according to the father, are exhausted by night, and potters are constantly covered by mud. Carpenters are not paid enough for their backbreaking work, and as gardeners age, the blisters on their necks begin to ooze pus. The father advises his son that the best profession is that of a scribe and goes on to advise him on how to succeed at that trade. In many ways, this text is reminiscent of modern parents advising their children to get a university education!

—Kevin M. McGeough

crafts rather than producing these craft objects themselves.

Ancient Workshops and Manufacturing—The Domestic Mode of Production

The vast majority of people in the ancient world were relatively self-sufficient, from a production standpoint. Even in the oldest urban states, most households produced their own food and clothing. Every member of the household would have contributed to the production of subsistence goods; without formal schools, children would have been expected to help around the house, learning subsistence skills by doing. Scholars of ancient economics call this situation the domestic mode of production.

In a domestic mode of production, the main concern of the members of a household is to produce enough goods to ensure the survival of all of the members of a household. The ability to feed and clothe one’s family was the best one could hope for economically. Economic calculations may have played an important role in many family decisions; for example, having more children could provide a larger labor force but also would create more individuals who have to be fed and clothed, creating less room within the house. Yet without social security programs, parents were reliant on their children to care for them in their old age.

In good economic conditions, a domestic production unit may have been able to produce a surplus, more products than they needed for consumption. This surplus could have been traded for other products, especially specialist products (such as metal tools) that were beyond the manufacturing capacity of a small household. Yet it may have been difficult to trade surpluses for specialty goods, since most of the products manufactured at home were foodstuffs, which could spoil relatively quickly. More often, though, a family would fall into debt. Since these small-scale producers lacked assets that they could pledge for a loan, they were compelled to pledge the labor of family members as collateral or as interest payments, a situation known as debt-

slavery. Once a family entered a debt situation, it could be very difficult to escape debt.

The kinds of productions that domestic producers could engage in were limited by the types of tools required and the level of training needed. Most production involved foodstuffs. Agriculture, animal husbandry, or any combination of these two practices may have been utilized by a family. Secondary food production was also done within the household. Grinding grains, slaughtering animals, preparing meat (for consumption or storage), and meal preparation were all household chores that took up a substantial proportion of time. Just as time consuming was the production of clothing. Textiles were usually made from scratch; hides, however, required more specialist equipment and access to large herds of animals. Sometimes, one or more members of a household would be craft specialists; these individuals would either produce goods within the home or work in factories and be able to supplement the household income.

Craft Production at Mehrgarh

Mehrgarh is one of the best-known and important sites in South Asia. It developed from an early farming settlement in the seventh millennium BCE into a prosperous town, flourishing until the beginning of the Harappan (Indus) period. The settlement provides an unparalleled picture of the development of the many crafts that reached their peak during the Indus civilization. From its early days, Mehrgarh's inhabitants worked flint and bone, made baskets and mats, and also made personal ornaments in steatite and copper. Simple pottery making began in period II (sixth millennium). Shell and gemstones were used to make jewelry, and copper was used for tools. Use-wear analysis on tools shows that

DRUDGERY

Alexander Chayanov was a Soviet economist (eventually purged by Joseph Stalin) who was particularly interested in the domestic mode of production and, in particular, how to motivate a peasant family to produce a surplus. The chief difficulty, according to Chayanov, was that work is boring, and people preferred not to do it if they did not have to. Therefore, external factors had to motivate a family to produce beyond a subsistence level. This is an important observation for ancient societies as well. What could compel an ancient family to produce beyond what they needed? There were not many products that could be purchased, so the acquisition of wealth probably did not play as significant a role as it does today. Taxation and enforced tribute (or the threat of punishment if these were not paid) would have been more important motivating factors.

—Kevin M. McGeough

wood and leather were also worked, although no artifacts in these materials survive.

Open-air working areas are known from period I (ca. 7000–5500 BCE onward). By period III (fifth millennium), distinct industrial areas within the settlement suggest the beginning of specialist craft production. From period IV (3600 BCE onward) Mehrgarh was supplying other settlements in the region with fine painted wares.

Flint, bone, and antler tools were abundant in the early periods, becoming less common later as copper tools came into regular use. Flint blades and bladelets were struck by indirect percussion, using a hammer and a small punch set against a prepared core. Some flints were re-touched by pressure flaking. Many were shaped into bead drills or awls for basket making and leather working.

Blades snapped into segments were glued with bitumen into wooden hafts to create sickles. Microliths were also used as sickle elements and as barbs and sometimes points on hunting spears and arrows; in periods VI–VII leaf-shaped jasper or schist arrowheads were used. Other flint tools included scrapers for preparing hides and blades for cutting or working reeds, other

➤ LAL SHAH

A specialized pottery-manufacturing site was discovered at Lal Shah, .6 of a mile (1 kilometer) outside the town, contemporary with Mehrgarh's final period, VIIC. Marks on vessels found here show that they were thrown on the potter's wheel, from which they were cut with a string. At least six updraft kilns were uncovered, along with much debris from pottery manufacture such as sherds from misfired pots. In these kilns the fuel chamber was cut into the ground, with above it the perforated floor of the upper chamber in which the pottery was arranged for firing. Such kilns were essential for firing fine pottery that required controlled conditions.

—Jane R. McIntosh

plants, wood, bone, and antler. Other types of stone were made into axes, adzes, and heavy tools such as grindstones.

In the early periods, bone was used particularly for leather-working tools such as awls, points, and scrapers and later for spatulae used on pottery. Most were made from sheep, goat, and gazelle metapodia. Ribs were used as pottery polishers and weaving and basket-making tools. Bone was also made into needles, punches, chisels, and hafts. Beads, rings, and pendants were made of bone and ivory. An elephant's tusk, grooved for dividing into pieces, was found in period II.

In the early periods, long bones were divided using the groove-and-splinter technique, allowing each to furnish several artifacts. Later, when metal tools became more common, only one object was made from each long bone. Bone artifacts were shaped and finished with flint scrapers and sandstone rasps.

Baskets and mats made by coiling or weaving local reeds or grasses survive only as impressions on other materials. Before pottery was developed, baskets coated with bitumen made watertight containers.

Discarded bones, many points and awls, and chunks of red ochre (used in preparing hides) identify one area as a leather workshop. Leather was used for making garments and many other objects. After period IV, there were fewer leather-

working tools, perhaps indicating a shift to woven textiles. Textile traces inside a bracelet of copper beads from a late period I grave are currently the world's earliest evidence of cotton thread.

A few beads found in period I graves were made of native copper, cold-hammered into a narrow strip that was wrapped around a rod. Although crucibles are known from period II onward, copper slag is absent: smelted copper was perhaps brought in as ingots, to be melted and cast into various objects here. Many traces of copper tools used on other materials, including saws, chisels, and drills, attest to the importance of copper from period III onward. Gold was also worked.

Beads, strung into necklaces and bracelets, were always important at Mehrgarh. In period I, copper, calcite, and steatite beads were made here, while those of shell, lapis lazuli, and turquoise were acquired from external sources. By period III, however, these materials were also worked at Mehrgarh along with carnelian and ivory and later agate and jasper.

The most common bead type was a small thin disk. Steatite roughly shaped by chipping and grinding into a hexagonal or octagonal cylindrical rod was then sawed into bead blanks. Each was perforated from both sides, using a flint drill in periods I and II, probably set in a wooden handle that was spun between the hands. From period III, cylindrical jasper or phthanite micro-drills were used with a bow drill. The disks were tightly strung together on a thread and rubbed against a grindstone with sand and water until the beads were worn circular. Spondylus shells broken into small pieces were made into disk beads in the same way. Other bead shapes, made from shell and a variety of gemstones, were worked individually by chipping, grinding, drilling, and polishing.

From period IIB, some steatite beads were heated to harden them and change their color from black or dark green to white. By period IV, some beads were coated with a copper-based glaze before firing, creating a type of faience; this required a controlled kiln temperature of around 1,000 degrees centigrade.

Shell bangles were also made, mainly using a single *Turbinella* shell. The apex and interior

parts were removed by sawing, then the bangle blank was smoothed and finished by grinding. Small shells were perforated as beads, and large bivalve shells were perforated near one edge as pendants.

A small amount of pottery began to be made in period IIA, built up from slabs of chaff-tempered clay. Clay might also be pressed into the inside of a basket; after drying, the clay vessel was coated in an outer layer of clay. In period IIB some of the pottery was finer and vessels were sometimes given a red slip. By period III, pottery was often of fine quality, made of a finely worked paste without vegetable temper, though chaff-tempered coarse-ware vessels also continued. Vessels were often finished by scraping with a bone spatula while turning on a tournette (slow wheel), then polished with a bone tool. Later, some vessels were also shaped on the tournette. It was not until period VII (around 2700–2500 BCE) that the true potter's wheel came into use.

Often the pots were painted. The designs became more elaborate with the appearance of a sophisticated technique of polychrome decoration in IIIB. Very fine clay mixed with haematite was used as paint. Those parts of the design that were to remain red were executed in paint mixed with a flux (perhaps potassium) that caused it to fuse at a relatively low temperature in the first firing, in oxidizing conditions. Heating to a higher temperature in reducing conditions then turned the remaining painted designs black and fused them. Finally, the vessel was again exposed to oxidizing conditions, returning unpainted areas to a buff color.

A potters' quarter of period V (around 3300 BCE) included an open area for bonfire firing and two storerooms with many finished pots. Other stores of pottery, fuel, pigment, kilns, pottery-making tools, and combs for decorating pots were also found. Mehrgarh's potters apparently produced fine wares and ordinary domestic pottery in separate workshops.

Ordinary pots were fired in a simple bonfire kiln. They were stacked over a layer of fuel and covered with sherds and a layer of dust and ash, then more fuel, and finally a sealing layer of clay, with the mouth of a broken jar in the top as a smoke hole and others around the edges to draw

in and circulate air. After lighting, the bonfire kiln burned for one to three days and was left for a further week to cool.

The people of period I produced a few very simple unfired clay figurines, crudely representing a seated human torso and legs. These gradually became less stylized, with the successive addition of breasts, a rod head, a pinched nose, and hair. Figurines began to be mass-produced in period VI; these were much more naturalistic, with bored circular eyes, spherical breasts, necklaces of applied clay, clasped arms, and a peculiar hairstyle or headdress. From late period VI, naturalistic hair was substituted, painted black, often with a red parting. Designs now included male figurines in turbans or with curly hair and various animals, particularly humped bulls. The majority were now shown standing rather than seated. Realism increased in period VII, with modeled, painted, incised, or appliquéd features, jewelry, hair, and headdresses. Huge quantities of figurines were produced at Mehrgarh in this period.

The Manufacture of Fine Stone Objects and Jewelry

From the period 4000–1000 BCE, increasingly sophisticated skills developed for the production of gems, jewelry, and fine stonework. The basis of stonework is abrasion, rubbing the stone to be carved with another substance over and over again, which is a lengthy practice. Prior to this,

➤ “ANCIENT KNOCKOFFS”—HARAPPAN STONEWARE

Given the difficulties involved in carving stone, it is not surprising that copies of ancient stone are found in the archaeological record. These skeuomorphs (objects of one material made to look like another material) were cheaper and easier to manufacture but evoked some of the qualities of stone. In the Indus Valley, stone bangles were luxury objects. A cheaper alternative would have been stoneware bangles, ceramic rings that were highly fired. These ceramics were either blackish-gray or pinkish in color, but they were covered with a white mottling that replicated the look of stone.

—Kevin M. McGeough

➤ JEWELRY FROM DAHSHUR, EGYPT

Pectoral with double portrait of Amenemhat III smiting an Asiatic beneath the wings of Nekhbet, Twelfth Dynasty. (Scala/Art Resource, NY)

Most of the Dahshur Jewelry, now in the Cairo Museum, was found by Jacques De Morgan during 1894–1895 in nearly intact tombs within the pyramid complexes of Amenemhat II, Senwosret III, and Amenemhat III at Dahshur. During 1994–1995, the Metropolitan Museum of Art team discovered additional pieces within the pyramid complex of Senwosret III. Belonging to the female members of the Twelfth and Thirteenth Dynasties (1850–1650 BCE) royal family, the jewelry made of various precious metals and stones exemplifies Middle Kingdom Egyptians’ superb skills, creativity, and taste in their decorative art. Similar jewelry was also found at el-Lisht and el-Lahun.

—Kei Yamamoto

stone tools were used along with abrasive substances, such as ground-up quartz or sand, to carve elaborate stone pieces. With the advent of metallurgy, these artisans could use copper and bronze tools to carve the stone, allowing for greater precision. The basic practice, however, remained the same. An abrasive substance was added to the stone being carved, and a drill was twisted back and forth on the spot until the appropriate depth was reached. Sometimes the drill was turned back and forth by hand; more effective was the use of a bow. By attaching a bow to the drill and moving the bow backward and forward (like playing a violin), the drill could be spun faster, more evenly, and for longer periods of time. Stone vessels, gems, and beads were worked on with drills powered by bows. Intricate designs were carved onto gems by gradually moving the drill horizontally across the gem. When these ancient gems are viewed under a microscope, the abrasions from the drill are often apparent. On poorly crafted gems, the circles left from the drill are readily apparent in the decoration.

Bead manufacturing is depicted on the walls of the Tomb of Rekhmire in Egypt; there the bead maker is shown drilling three beads at once. Other evidence comes from archaeological excavations at the site of Chanhudaro, in the Indus Valley. There, a bead-manufacturing workshop was excavated. At Chanhudaro, long carnelian beads were manufactured from materials that were imported from mines in far-off Gujarat. Long pieces of carnelian, after having been brought to Chanhudaro, were left out to dry in the sun for several months. Given the seasonal monsoons in Pakistan and India, there would have been a relatively tight window in which to do this. After drying, the carnelian was heated in ovens to make it easier to work. The outsides of the beads were carved using pressure flaking (a gradual exertion of pressure on the stone) or through indirect percussion (hammering another tool so that it rubbed against the stone). A long drill was then heated and, using a bow, drilled through the bead (possibly while the bead was under water, which would have sped up the process). Given the length of these pieces of carnelian, it would have taken at least 24 hours

to drill a hole straight through. One estimate for the length of time it would have taken to manufacture a typical Indus Valley belt is 480 days!

Nonstone jewelry that has survived archaeologically is mostly made of metal (often, as is the case today, metal and stone were combined to create pieces of jewelry). Metal casting was very common, as was hammering sheet metal into a desired shape. Wire for necklaces was hand wrought, and gilding could be used to make inexpensive materials look more expensive. Much Egyptian art consists of wood gilded with gold, giving the objects a lavish appearance. Enameling, in which powdered glass was heated onto a metal surface, thus fusing the two substances together, was also common.

The First Glass

Glass is a substance that retains some of the properties of a liquid after it has been cooled to a solid state. The first glass used by humans was obsidian, a naturally occurring glass. Obsidian, which is formed when volcanic lava cools very quickly, can be extremely sharp and is very versatile. The first synthetic glass was produced in Egypt. These first glasses, which took the form of ceramic glazes, were probably accidentally discovered during the manufacture of pottery.

For about 1,500 years, glass was used mostly as a glaze. By the Middle Bronze Age in the Near East, glass vessels started to be formed. At this

FAIENCE

While the word "faience" has different connotations in different contexts, Egyptian and Indus Valley faience are types of nonclay ceramics that are glazed and are composed primarily of sand or crushed quartz mixed with lime or a similar substance. Egyptian faience has a blue-green color and was widely used in ancient Egypt due to its relative ease of manufacture, ease of shaping, and brilliant color. The compounds are first ground into powder and then mixed with water into a paste that can be easily shaped by hand. Sometimes, faience was mixed with alkali salts so that when the object was put into a kiln, the salts rose to the surface, giving the object a shiny look. Other times, the object would simply be buried in a mixture so that afterward, when the object was fired, a chemical reaction would occur, fusing the two substances. When used as a ceramic glaze, it is painted directly on the pottery before the vessel is fired.

—Kevin M. McGeough

time, glass appeared throughout the Near East, the eastern Mediterranean, and the Indus Valley, although the finest-made glass was produced in Egypt. Most glass was created in small workshops. In these workshops, glass chunks were created by melting all of the ingredients together and quickly cooling them. Sometimes the first glass would only be melted at a very low heat. After cooling, it would be ground up into a powder or paste and then heated again until melting, creating a much finer quality of glass. These chunks of glass could later be melted and formed into the desired shape.

Glass beads were made by forming the glass around a rod, which could be removed after the glass cooled. Glass figurines were melted in molds, creating elaborate designs. Glass inlays would be cut from long sheets of glass; these pieces of glass would then be inserted into larger pieces of art, furniture, or architecture. Glass vessels were formed around a core that could withstand heating but could also be removed again after cooling, usually a combination

of metal and wood or ceramics. While the glass vessel was still on the core and still hot, it would be marvered (smoothed) along a flat surface. Decoration could be added at this time by winding threads of molten glass along the edge, placing lumps of molten glass on the sides, or attaching cooled glass handles with molten blobs of glass. Mosaic vessels were formed by assembling small rods of different-colored glass (called canes) over a solid core. The canes were then covered by a solid mold, and the whole object was heated. After being heated, the mold was removed, and the surface was marvered. The end product was a multicolored glass vessel with a geometric design.

■ Introduction: Taxation and Tribute

Taxation and tribute were two major sources of income for the governments of ancient polities. Taxation refers to regularized payment owed to the government by members of the polity. Payment was made in a number of different media, often either goods or services. Compulsory labor and military service were arguably the most common types of regularized payments. Customs dues on imports, which can be considered a type of taxation, were also levied in certain situations. During this period (4000 to 1000 BCE) taxes were not intended to pay for infrastructure or other services that the government performed for the population at large. An ancient Egyptian or Shang dynasty peasant (in China) would not have thought to ask for a reckoning of how the government was spending "their taxes." These were payments that they were forced to make through threat of violence or legal sanction. It is better to think of ancient taxation as a means that the government had of skimming off the top of economic producers within the polity. These payments could be used by the governments at their own discretion. Typical uses included the payment of military expenses, the construction of royal monuments, and the payment of tribute to other pol-

ities. For the most part, tax revenue was used by the king at his own discretion for his own maintenance and for his own pleasure.

Tribute, on the other hand, typically refers to irregular (or semiregular) payments made between different polities, almost always from a subordinate polity to a more powerful one. The two polities involved in the transaction may have both been independent states, or one of the polities may have been a region that was formally subsumed into the empire of the more powerful polity. These tribute payments were usually referred to as gifts. The more powerful state may have demanded a "gift," or the weaker state may have offered a "gift." In the interstate correspondence in the Near Eastern Bronze Age, weaker states referred to themselves as the "sons" of more powerful states, whose leaders were called "father." This language of gifting and familial relationship was used to smooth over the tribute transaction and to reinforce the relationships that were being built by the tribute payment. Smaller polities often benefited from making these payments, as the relationship with a larger polity could have brought with it security from other rival states as well as access to goods and services available within that larger polity. Items

that were given as tribute varied dramatically, from staple crops and mineral resources to exotic goods (especially products derived from animals available only within the region of the smaller polity). Military service or specialist labor was sometimes provided, and princesses were sent as tribute to become wives in the royal court and further cement the relationship between the two powers.

Egyptian Taxation

The ancient Egyptians are famous for their monumental architecture, such as the pyramids at Giza. Such projects were undertaken by the state and were expensive, requiring thousands of laborers, raw materials for building, and food and lodging for the workers. In order to pay for their public works projects, the Egyptian state collected taxes. Ancient Egypt was a nonmonetary society, and as such things were bought and sold using goods such as food, minerals, or household items. The same is true of wages. A worker was paid in the form of food items (grain, beer, meat) or other objects of necessity (linen, wicks for lamps, etc.). Taxes to the Egyptian state were paid in the form of grain, minerals, meat, leather, textiles, and labor. Called *corvée* labor, people who had to pay their taxes as part of mandatory labor worked on state-run projects such as building a temple, digging a canal, or the like. The collected taxes paid for such things as temple endowments, military garrisons, royal works (e.g., building tombs), the upkeep of the royal household (e.g., all the palaces and their staffs), and governmental employees.

The evidence for taxation in ancient Egypt goes back to the First Dynasty. The Palermo Stone written in the Fifth Dynasty lists the kings from the First through Fifth Dynasties and their tax assessments and census data. Because so many of the taxes were paid using agricultural goods, it was essential for the Egyptian government to know how good the harvest was going to be each year. They did this by assessing each field throughout Egypt according to its potential to be flooded. Those fields that were flooded yearly by the Nile could produce much more grain than those that required artificial irriga-

tion. Nilometers, placed at intervals up and down the Nile River, recorded the height of the river. Complex equations then determined how much the government could expect at harvest time. This, in turn, determined what that year's taxes would be.

A large bureaucracy was created in order to collect taxes and then distribute the goods to the appropriate people and institutions. The department of the granary collected grain taxes, while the treasury of the pharaoh collected everything else. This was coordinated and overseen by the vizier, the highest public official after the king. District officials and town mayors collected taxes at the local level and delivered them to the vizier. Failure to deliver the expected taxes meant harsh punishment at every level. The Sixth Dynasty tomb of vizier Khentika depicts the punishment of five district governors accused of misappropriation of taxes. A person failing to show up for *corvée* duty could be sentenced to serve the government forever.

Throughout Egypt's history it controlled many countries around it. While several of these countries remained largely independent, they paid the Egyptian state tribute (a form of tax) as a show of submission. Refusal to pay tribute was seen as rebellion and could lead to invasion and destruction. Foreign tribute helped Egypt obtain many of the basic goods that it did not produce, such as lumber and gold. Lebanon sent cedar trees, Syria sent boxwood, Nubia sent gold, and grain came from Canaan/Palestine.

No one likes to pay their taxes, and the ancient Egyptians were no different. A tax exemption from the king was highly sought after. Exemptions were most commonly given to temples but could go to individuals. A temple with a tax exemption did not give any revenue to the state, and their employees did not have to report for *corvée* labor. Interestingly, although most temples had lands from which they could sustain themselves, many also received endowments from the state that were funded using taxes.

Mesopotamian Taxes

In the earlier third-millennium Mesopotamian cities, substantial estates were owned and administered by temple authorities and kings. Economic texts mainly record the official receipt, storage, and distribution of agricultural produce; the management of state-controlled craft production, particularly of textiles; and details of officially sponsored trade. Land was also privately owned, and as the millennium unwound, kings came increasingly to control land and the bureaucracy as shepherds of the people, answerable to the tutelary god for the well-being of city and state. The most detailed and comprehensive administrative records come from the reign of the Ur III king Shulgi (2094–2047 BCE), when the state had almost total control over the econ-

omy. In succeeding centuries, private enterprise grew in importance. Merchants' private archives give an insight into the organization of production and the flow of goods and materials.

Several mechanisms ensured the movement of goods and services between producer and state or employer: taxation or tribute, rent and the repayment of investments, and waged or compulsory employment. More haphazardly, booty from warfare also filled the state coffers and licensed looting the baggage of private soldiers and army officers.

In the early city-states, offerings of agricultural produce and other commodities were made to the temple; in effect, these were taxes to support the state, which was viewed as the tutelary god's personal estate, maintained by its citizens. A late-fourth-millennium alabaster jar from Uruk vividly depicts a donative ceremony, where people in procession bring baskets and jars of grain and fruit as well as animals and artifacts, which the priest presents to the deity. Making such gifts symbolized the individual's membership of and participation in the community. At a higher

➤ INVESTMENT IN MESOPOTAMIA

Considerable state and private revenue came from rents, investment, and landownership. Both temples and kings were major landowners, and in the case of conquered territory, the state might claim ownership of all the new land or confiscate large tracts from defeated leaders. These lands were granted to members of the royal household, powerful nobles, military or civil administrators, and temple dignitaries, and smaller holdings were granted to lesser officials and state or temple employees in return for military or various forms of civil service. The lands could be farmed directly by these people and their households, managed for them by local officials or smaller landowners, or rented out to peasants. Areas of state land might also be rented by private entrepreneurs, particularly in later times. Land could also change hands privately; the price of a field in Sumerian times was equivalent to a year's anticipated yield, although typically its rent was between a quarter and half of the projected or actual yield, assessed annually. Similarly, contracts were negotiated between

pastoralists and the owners of herds and flocks. More complicated agreements were made whereby a return was not expected within a single year. For example, according to Hammurabi's law code, when land was rented to create an orchard, no rent was payable for five years, at the end of which the land, with its fruit trees, was divided, half going back to the landowner and half to the tenant, with the proviso that the latter include in his share any part of the plot that he had failed to plant with trees. Both state and private investors participated in financing trading expeditions, putting up capital or making loans against interest from the eventual profits. Surplus goods, materials, or foodstuffs accumulated by the temple or palace from their taxes and tithes and from their lands and industrial activities could be sold to merchants, often as futures not yet received by the authorities, introducing legal complications if their tenant or employee failed to produce the goods to which title had been transferred.

—Jane R. McIntosh

level, the Sumerian city-states recognized Nippur, seat of the chief deity Enlil, as their religious and symbolic center, and all contributed to the upkeep of Enlil's temple, the Ekur, by making offerings on a rotating basis. A parallel institution may have united the city-states of the middle and upper Euphrates around the temple of Dagan at Tuttul, and Subartu (later Assyria) may also have had such a confederacy. Such offerings continued later. Under King Shulgi, the provinces, which largely corresponded to the traditional city-states, took turns contributing to the upkeep of Enlil's shrine, in proportion to their wealth. Enormous numbers of animals and quantities of grain and other produce were centrally accumulated and distributed as necessary to maintain the personnel of the temple, bureaucracy, and state industries; these offerings (taxes) were known as *bala*.

The state exacted revenue through other methods and for other purposes than cultic ones. The Ur III empire controlled not only the core region of city-states but also a periphery of conquered lands along its eastern and northern edges. From these, revenue came in the form of rent (*gun mada* tax) paid by their military governors for the lands that they held and from which they in turn extracted revenue in kind. A similar arrangement had operated under the earlier Akkadian empire, where large areas of confiscated land were granted to Akkadian military colonists. In later times, defeated states were left under puppet native rulers or placed under Mesopotamian governors who paid tribute or taxes to the state, collecting these from their own subjects.

A variety of private activities could attract taxes. For example, the merchant houses that conducted trade between Assur and Anatolia in the nineteenth century BCE paid export taxes on their goods when they started out from Assur and import duties to the Anatolian authorities.

Minoan Palace Economy

One can expect that at any given time, at least 95 percent of the Aegean economy was dominated by agriculture. Independent or semi-independent farmers raised grains, fruits, and vegetables; pastoralists grazed sheep and goats, and possibly larger cattle, for milk, meat, wool, and even labor; and hunters and fishers supplemented the daily fare. In the home, women and probably children spun wool, wove cloth, sewed clothes, prepared meals, and made the majority of the pottery for household consumption. Trade had existed since the Neolithic period, when obsidian from Melos made its way to all corners of the Aegean. By the Early Bronze Age, copper and then tin appeared throughout the Aegean, copper most likely from Cyprus and tin from much, much farther afield. Also there is evidence that already during the Early Bronze Age, a more organized extra household economy was beginning to develop throughout the Aegean. In Crete, monumental architecture began to appear in Early Minoan II Palaikastro and in Early Minoan III Knossos, revealing the early stirrings of an organized labor force. In Greece, the Early Helladic II town of Lerna had what appears to have been a large central storehouse, where excavators found a collection of clay sealings probably used for identification of producers and for redistribution. Henceforth, one might speak of them having a palace economy, an economic system in which a strong centralized power controlled the production and distribution of non-domestic goods and, presumably, services.

In Palatial Crete, this centralized power consisted of the palaces and, later, the villas. According to Branigan, the five primary economic

functions of Minoan palaces from Middle Minoan III to Late Minoan I were (1) production of manufactured goods, (2) consumption of food and manufactured goods, (3) regulation of local and internal exchange, (4) regulation of international and external exchange, and (5) use as depositories.

The production and storage of manufactured goods are evident from the digs at Phaistos and Mallia. Excavations of the earliest phases at Phaistos (Middle Minoan I–Middle Minoan II) revealed two areas dedicated to economic activity. Unit A contained several large storage vessels originally filled with foodstuffs, including liquids such as wine and oil. Nearby Unit B was the palace workshop. Here, excavators found tools used for stoneworking (a lapidary workshop), several loom weights (a weaving workshop), and two potter's wheels (a ceramics workshop). Clay sealings from a smaller room in Unit B may indicate where finished products were processed for storage or export. By the second phase of the palace, there were even more food storage vessels present, and an actual archive room was created.

Similar finds appeared at Mallia. In the northwest quarter of the palace, excavators discovered obsidian, soapstone, and a reddish stone called rosso antico, all evidently part of the lapidary workshop. A potter's workshop was also present within the palace walls. During the Middle Minoan II period, a bronze smithy was located just outside the palace walls. It is actually surprising that such an industry would be so close to any residential quarters, considering the unpleasant fumes given off by the work and the rather high potential for fires. Nevertheless, by the Middle Minoan III period, the palace walls were actually extended so that the smithy was located within the palace itself. Clearly, this was an industry over which the palace wanted to keep very close control.

The role of Minoan palaces as depositories and regulators of local distribution and trade may be seen in the *koulouras*, large stone-lined pits located at Knossos, Phaistos, and in a slightly altered guise at Mallia. There is continued debate as to the purpose of these huge storage bins. Evans suggests that they were rubbish pits. Some modern scholars believe that they were giant tree planters. But the usual interpretation

is that they were for grain storage, with the *koulouras* at Knossos being able to hold enough grain to feed 1,000 people and the *koulouras* at Phaistos being able to hold enough for 300 people. In such a case, the palace would have received a substantial portion of the agricultural produce of the surrounding farms, stored it, and then distributed it to the more specialized non-agricultural populace of the palace region.

Palatial control over foreign trade is more difficult to prove archaeologically, as there is often no way to determine where on Crete any specific item found abroad was made. One argument often brought to the fore is that only the palaces would have the capital (to use a modern term) to finance the goods and shipping for long trade journeys, not to mention to handle the risks of possible sea wrecks. Another argument, however, lies in the nature of the Minoan goods found abroad. For example, Kamares Ware pottery has come to light on the coasts of Cyprus, Egypt, Palestine, Canaan, and Syria. This Kamares Ware is clearly a product of palatial manufacture. The ceramics from before and after the classical Kamares wares are clearly local creations, Knossian Ware being distinct from Mallian Ware. By contrast, the Kamares Ware made in the palaces is similar from palace to palace but is utterly distinct from the provincial wares. Therefore, we might argue that the Kamares wares found in the Near East are definitely from palatial production centers. The number of foreign goods stored in the palaces, especially Zakro, also gives evidence for the palatial control of international exchange.

Mycenaean Palace Economy

The Mycenaean palatial economy did not differ in many respects from the Minoan. In fact, the Mycenaeans seem to have taken over the trading posts once used by the Minoans, as well as the palace of Knossos, after 1450 BCE. The fact that the Mycenaean palaces fulfilled the same roles as the Minoan is evident from the archaeology, which reveals palaces on the Greek mainland functioning as producers and storers of manufactured goods. This is particularly evident at the palace of Pylos in southwestern Greece. Surrounding the *megaron*, or main throne room, was a series of rooms used for the storage of oil and ceramics. One room contained 850 pots of varying shapes, and another contained a total of 2,853 drinking cups. To the east and northwest of the palace proper were industrial buildings containing storage jars, pieces of bronze, clay sealings from "packaged goods," and even bits of ivory. Farther on were remains of a potter's kiln with discarded bits of pottery lying about it.

Archives discovered at the Mycenaean palaces containing records written in Linear B, the early Greek script used by the Mycenaeans, give further insight into the functionings of the Mycenaean palace economies. The palaces maintained extensive control of the nondomestic areas

of production through careful control of the acquisition and distribution of raw materials, the maintenance of several key personnel in the palace industries, and the tallying of produced goods. The similarities and contrasts among three separate industries will serve to show the various machinations of the Mycenaean bureaucracies.

Textiles were an important Mycenaean commodity. Beyond just the household production of cloth and clothing, the palaces produced textiles for their own use as well as for export. Numerous Linear B tablets record the various components of this textile industry. For example, the Da-g and Dn series of tablets from the archives at Knossos show that some 80,000 to 100,000 sheep were grazed in central Crete. Some tablets show how much wool was expected from these sheep; others show how much wool and offspring were expected (it seems that one group recorded males, while the other recorded females). Later, the Dk and Kl tablets revealed that these flocks produced about 30–50 tons of wool, which was collected and brought to palatial workshops, where the Lc tablets show how this wool was allocated. Here, the Linear B A-series of tablets reveals that the workers in these workshops were predominately women, usually identified only through what they did or where they were from. Many women were listed with girls and/or boys associated with them. Perhaps they were mothers working with their children or older women training girls and boys too young yet for other employment. It is clear from these documents that food rations were provided for the textile workers. This plus their namelessness and the fact of their foreign origins may suggest that the workers were slaves, although the word *do-e-ro* (= *doulos* = "slave") does not appear.

The L series of tablets covers the target production set for these worker groups, including the allocations of raw materials that they were given to process. These allocations refer to the still rather ambiguous word *ta-ra-si-ja* in the tablets. Currently, researchers think that the *ta-ra-si-ja* were individual units of a raw material, be it wool, bronze, or possibly some other material, that the palace gave to workers to turn into finished products, in this case fabric of some sort. When the finished products were collected

by palace officials, the amount of fabric (or whatever the commodity) was reckoned against the amount of the original ta-ra-si-ja to be sure that all necessary materials were used appropriately. In this way, the palaces could administer and control workshops and factories that were not necessarily located within the palaces themselves.

In contrast to the textile industry, bronze smithing seems to have been under less direct palatial control, and the smiths themselves had a higher status than the textile workers. Unlike the textile industry, not all bronze smiths received raw materials from the palaces (although many did), suggesting that there was also some noncentralized free trade taking place. The smiths likewise received no rations from the palaces, and in many instances they actually owned their own slaves.

It is interesting to note that the palace bureaucracies kept track of the smiths to whom they did not send allocations, showing that the centralized powers kept at least some degree of watch and/or control over what may have been the free sector. It is of note that no smithies have yet come to light in Mycenaean territories except one at Nichoria dating back into Middle Helladic times. This suggests that the smithies were located away from the more populated areas, no doubt due to the fumes produced by the industry.

Finally, let us consider a third, highly specialized industry: perfumed oil. The tablets referring to this industry, the Un series, mention what appears to be a master perfumer who worked at the palace itself and who used several different commodities in the production process, including oil, flowers and spices, wool, and even wine. However, the term ta-ra-si-ja, “allocations,” never appears in these perfume production tablets in spite of the fact that it seems to be very much a palace-centered industry. This is probably because of the highly supervised nature of the industry itself. One might imagine the master perfumer working (and possibly living) at the palace, organizing his materials and disposing of his perfume all within the very hub of the bureaucratic system and therefore without the need for an official to keep track of goods sent outside the palace to him. Such a sys-

tem would also be applicable to other industries that made use of specialty items (flowers, spices, precious stones) that were processed at the palaces themselves by master craftsmen and crafts-women. This stands in contrast to the more spread-out and single-material industries, such as the bronze smiths who required bronze and the weavers who required wool or linen. Only these latter fall into the economic category of the ta-ra-si-ja.

These three examples show a spectrum of industries in the Mycenaean economy. At one extreme were industries such as textiles, for which many steps were required between the most basic raw materials (sheep) and the finished product (fabric); in which many, if not all, of the workers in the industry were maintained directly by the palaces through rations; and in which there did not appear to be a private industry operating alongside the palatial one (except, of course, for basic domestic textile production). We might call this a state-owned monopoly based on factories. We might see this as a more freelance industry, with independent or semi-independent smithies doing contract work for the palaces. Finally, there were the luxury item industries, such as perfumed oils, in which the workers worked directly in the palaces in positions that must have attained considerable prestige.

Shang Taxation and Tribute

Since the rise of a communist government in China, scholars have spent much energy studying the relationship between the state and the laboring classes in antiquity. The Shang dynasty

provides the earliest textual evidence for this issue. Given the ideologically loaded nature of this question, any analysis of this problem can be fraught with difficulty. Regardless of modern ideology, it is apparent that the Shang kings were able to marshal a large labor force and had significant authority over the people of the kingdom. The ability of the state to perform human sacrifice demonstrates a significant amount of power. The monumental walls of the Shang cities are a remnant of this state ability to control a large labor force. The construction of such large walls (as well as the platforms on which the palaces of Shang cities were built) would have been impossible without a ready supply of labor.

The residential areas of Shang cities show a wide variety of personal wealth. The most numerous houses are the houses of the poorest. These poorer city dwellers may have been members of the royal workforce. Information about the royal workforce is rather laconic; most of it is gathered from brief notices on divinatory texts, leaving much room for interpretation. It is clear from these texts that lower-status individuals were conscripted for military service, outfitted by the royal armory, and organized into units by royally appointed officials. Laborers were called *zhong* (which translates as “the many”). What exactly was connoted by this term is a heavily debated point. The word *ren* (meaning “person”) also appears in the oracular texts in reference to state service. This term appears to be more neutral than *zhong*, but once again the exact semantic range eludes modern scholars. There is no terminology for slaves, and there are no texts describing the explicit sale of humans. However, the facts of human sacrifice and conscription may mean that distinguishing between slaves and free laborers in Shang society is simply splitting hairs.

A stratified social structure is evident at the intercity level as well. The Shang kings reigned from various capitals but tied the kingdom together through a patriarchal lineage system. As part of the lineage system, smaller localities (and allies that were not formally incorporated into the empire) were compelled to provide the Shang king with tribute. Human labor was an especially important type of tribute; both productive service and military service were compulsory.

Shang dynasty sacrificial site, Zhengzhou, Henen, China.
(Lowell Georgia/Corbis)

Humans for sacrifice were also important tribute offerings. The most frequently recorded forms of tribute were turtle shells and cattle scapulae, the raw materials necessary for divination practices. While there was probably no formal, consistent tribute system, the ability of the Shang kings to exact tribute furthered their political and economic power.

Lords and Peasants in the Classic of Songs

The *Classic of Songs*, *Shi jing* (*Shih ching*), is the oldest and most revered collection of poetry in a 3,000-year-old literary tradition that places an especially high value on poetry. These songs, primarily from the 9th through 7th centuries BCE, include themes and images that were rooted in even earlier folk tradition and continue to resonate with readers today. Among the 305 poems collected in the *Classic of Songs*, there are numerous folk songs and poetic accounts of daily life that describe the labor, love, experiences, and obligations of aristocrats, officials, and common people. While many early sources in China and elsewhere are written by and about rulers, these songs also transmit folk traditions and commoners' perspectives including a vigorous voice of protest against the exploitation of peasants.

The traditional understanding of the purpose of this collection of songs relates to political di-

mensions as Zhou (Chou) rulers were said to have sent officials to gather these songs in order to assess the welfare and attitudes of commoners. Just as scholars look to these ancient poems in modern times to try to understand the daily life, concerns, and expressions of Chinese people in the Zhou era, this traditional interpretation of the motivation for gathering the songs suggests that rulers of that time were also looking to folk songs as reflections of peasants' sentiments. Admittedly, other traditional attributions about the *Classic of Songs*, such as the idea that Confucius compiled this collection, are quite unlikely. However, regardless of whether the collection came together in accord with that traditional understanding of officials scouring the countryside to survey the populace through their songs, the *Classic of Songs* remains a rich early source for insights about people in the Zhou era.

Each of the following verses from the *Book of Songs* is followed by the initials of the translator (see "Further Reading") and the "Mao num-

► USING ANCIENT CHINESE SONGS AS HISTORICAL EVIDENCE

Traditionally, some of these Zhou (Chou) era songs were attributed to the Duke of Zhou before 1000 BCE, and Confucius has been credited with redacting the *Shi jing* in the middle of the first millennium BCE by selecting and ordering 305 poems from among thousands. Recent scholarship discounts both attributions, as most of the songs were composed from the ninth to seventh centuries BCE, and it is evident that the process of gathering this anthology from a wide array of earlier poems and folks songs preceded the role of Confucius. In fact, Confucius made reference to these songs in his *Analects*. Nonetheless, some of the influence of the *Classic of Songs* stems from the traditional links to the Duke of Zhou and to being among the core Five Confucian Classics. As suggested by the English title, *Classic of Songs*, most or all of the poems/songs (*shi*) in this book/classic (*jing*) were lyrics with accompanying musical scores that have since been lost. The *Shi jing* is alternately translated as the *Book of Odes* or *Classic of Poetry*. However, *shi* does not mean poetry, odes, or songs in general; rather, it is a term for Chinese classical poetry. This form was dominant when the *Classic of Songs* was compiled

circa 600 BCE and remained influential for another 2,500 years. Despite the antiquity of the *Classic of Songs*, the themes and imagery are readily accessible. Some verses were originally folk songs, and others had different origins. Although often adapted to conform to a more consistent poetic form, the various origins and themes are still discernable as distinct types. Along with "Hymns," which may have been ritually chanted in religious ceremonies, there are Greater Elegances, Lesser Elegances, and Airs of the States. While the Greater Elegances include odes to ancient heroes and events, the last two categories offer more glimpses into daily life, with the Airs of the States offering the most direct insight into the daily life of common people. These are the most numerous, and the first 160 of the 305 poems in the traditional Mao order fall into this category. The Airs of the States poems are also the most accessible due to their simpler style and everyday themes, including complaints about peasants' hardships. The Lesser Elegances overlap with this category but are loftier in tone and somewhat more likely to reflect historical events or provide glimpses into aristocrats' lives.

—John Harding

ber”, which identifies the song according to the dominant order for songs in the collection. This order, which was established more than 2000 years ago by two editors named Mao, corresponds to the four divisions of song types. The following song epitomizes the bluntness of a hardly-veiled critique leveled by peasants against their feudal lords and related officials, who are depicted as ungrateful rats rather than esteemed superiors.

Big rat, big rat,
don't eat my millet!
Three years I've served you
but you won't care for me.
I'm going to leave you
and go to that happy land,
happy land, happy land
where I'll find my place.
Big rat, big rat,
don't eat my wheat!
Three years I've served you
but you do me no good.
. . . Big rat, big rat,
don't eat my sprouts!
Three years I've served you
but you give me no comfort. . . (BW, 113)

While the peasants' cries of “big rat” offer blatant complaints of mistreatment and woe, there are other songs ostensibly about something else that have been interpreted as criticism of oppressive rulers. The following is such a song where the common theme of love has also been understood as distress about the pitiless government and perhaps even a call to leave their uncaring rulers for another state.

Cold is the north wind,
the snow falls thick.
If you are kind and love me,
take my hand and we'll go together.
You are modest, you are slow,
but oh, we must hurry!
Fierce is the north wind,
the snow falls fast.
. . . If you are kind and love me,
take my hand and we'll ride together.
You are modest, you are slow,
but oh, we must hurry! (BW, 41)

Some verses describe the work of the common people. For example, Mao #154 is a long song detailing cyclical obligations where each month's tasks are in accord with the seasons. Another verse, Mao #112, contrasts the peasants' agricultural occupation with the lords' hunting. This contrast also suggests tensions both because the lord eats the peasants' produce and because his game and hunting grounds are not available to the peasants for their own welfare.

The two poems below are from the “Lesser Elegances” section and criticize a king's misrule. The first describes how a virtuous ruler is “a pattern for the people” before contrasting such a model with this degenerate successor.

The one of today is aroused and seduced by
disorder in government.
He overturns his own power.
He abandons and dissipates himself in
wine.
You devote yourself only to dissipated
pleasures.
You do not ponder your lineage.
Why do you not apply yourself to seeking the
[Way of] former kings
so that you could hold fast to their enlightened
law? (PG, 256)

The second poem includes the reproach to a ruling lord that “People had land and fields but you possess them” among a litany of complaints that are characterized as “Heaven on high” sending “down these great horrors” as punishment for a mismanaged state (PG, 264). The emphasis remains on the king not fulfilling his obligations as king, but in this song, too, the mistakes, neglect, and abuse of the lords translates to suffering for the peasants.

■ Introduction: The Myth of the Temple Economy

A common misconception about ancient Mesopotamia, and particularly about the people living in the region often referred to as Sumer, is that the economic life of these people was organized around the temple. Early historians who studied Mesopotamia were influenced by the nineteenth-century evolutionary models purporting to describe the development of civilization. These scholars often interpreted ancient economic practices according to the model rather than through strict analysis of evidence. They assumed that the earliest economic systems reflected egalitarian ideas. As a society became more complex, temples and religious organizations would take over as the economic organizers, eventually to be supplanted by political authorities, such as kings or other governmental authorities. This type of evolutionary framework was appealing to early historians since it was simple to understand and easily fit the evidence at hand. Now, however, most historians find this framework too simplistic, and indeed the more evidence that is found, the more difficult it is to reconcile this evidence with generalized evolutionary models.

It is easy to understand why the first Sumerologists argued that the earliest complex economies were run by religious institutions. Many of the oldest surviving Sumerian documents are tablets from ancient temples. These tablets are not ritual or mythological tablets, as one might expect tablets from a temple to be. Instead, they are economic documents, receipts or contracts that record the exchange of barley, animals, and other agricultural products. These tablets are of-

ten very difficult to read, and usually no information is preserved about why the tablets were inscribed or why it was necessary to record this information. Since there is so much room for historians to interpret these tablets, numerous arguments have been made about what kind of economic transactions they represent and why they were written.

Most historians now working with these materials no longer believe that the temple organized the ancient economy. Instead, historians understand that religious institutions engaged in complex economic activities and practices, activities and practices that would be more often associated with a farm or ranch today. These temples did not control the ancient economy but were simply wealthy organizations that played a prominent role in ancient economic life.

—Kevin M. McGeough

The Economy of Mesopotamian Temples

Temples and temple complexes are far and away the largest structures found at Mesopotamian sites dating to the fourth and third millennia BCE. Sites such as Khafajeh had temples that took up a vast amount of space and used a significantly larger number of building materials than any other buildings. These early temples contained a much wealthier material culture than other types of buildings, most notably the elaborate statuary that was the focus of early Mesopotamian ritual practices. Given the amount of effort expended to construct such monumen-

tal buildings and the sophistication of the wealth and materials found inside, the archaeologists and historians who uncovered these temples in the early twentieth century argued that the religious leaders must have been in control of the economy. Furthermore, many documents found within these abandoned temples attested to a high degree of economic organization. Scholars working in the early twentieth century argued that temples dominated the economy of early Sumerian cities and controlled the economic actions of the people who lived in proximity to the cities.

In contrast to the large temples filled with riches and elaborate goods, what little domestic architecture these early archaeologists uncovered was simple and small. Goods found within the houses were usually utilitarian and included pottery, food manufacturing equipment, and textile manufacturing equipment. The materials found within each house seemed similar, and little social differentiation was readily apparent.

Based on the situation in these early Sumerian sites (large wealthy temples alongside small poor dwellings), early historians described the Sumerian economy as a temple economy. In a temple economy, it was believed that the highest meaningful level of governance was at the city level. Each city was owned by a particular deity. The priests and temple personnel organized production and distribution within the city and in its hinterland, creating a planned economy that Henri Frankfort described as theocratic socialism. The temple owned all of the means of production, from ploughs to draft animals to seed for crops. These resources were distributed to the various individuals as they needed them during the year. The goods produced with these resources were given directly to the temple, and the temple then redistributed these goods to the population at large. It was not only agricultural workers who participated in this temple economy scheme but all workers: fishermen, metalsmiths, and potters. In the reconstructions of some scholars, each worker kept the surplus of goods that he or she produced after reaching a quota required by the temple. Redistribution then was not on such a large scale but would occur periodically at feasts or at certain holidays.

➤ SUMERIAN TEMPLE RECEIPTS

Sumerian economic texts are particularly difficult sources for historians to work with. Usually written quickly, these clay tablets contain minimal information, usually a simple record of a particular economic transaction. The rationale for the transaction is almost never recorded, and only rarely is any information given about the individuals or institutions involved in the transactions. The following texts are translations of tablets found in a drainpipe at the site of Fara describing the deliveries of goats to various temples in the city by a man named Urni. Texts such as these are typical of the materials Sumerologists use to reconstruct ancient economic activities.

Text 1. One kid delivered to the temple of the goddess Sud; one kid delivered to the temple of the God Enlil. Delivered by Urni.

Text 2. Two kids delivered to the temple of the goddess Sud; one kid delivered to the temple of the God Enlil. Delivered by Urni.

Text. 3. One kid delivered to the temple of the goddess Sud; one kid delivered to the temple of the god Utu; one kid delivered to the temple of Enlil. Delivered by Urni.

—Kevin M. McGeough

One of the most compelling arguments in favor of these models was the huge amount of economic records that were recovered from these temples. While the amounts of ritual, religious, and mythological texts found in temples varied from site to site, what almost always remained the same was that there was a significantly higher proportion of economic tablets recovered from these temple complexes. Most of these documents recorded amounts of agricultural products, amounts of crafts, and the names of various people, presumably people who owed or were owed products from the temple. It seemed clear to these early scholars that at least from an administrative perspective, one of the major priorities of these early temples was the organization of economic activities: agricultural production, crafts production, textile production, and the redistribution of such products. Recent scholarship no longer holds this interpretation of temple economic activities as tenable.

The Reaction against the Temple Economy

Recently the temple economy models have come under attack by Mesopotamian scholars, and it has become apparent that these early scholars misunderstood the evidence. Early historians who studied Mesopotamia were influenced by nineteenth-century evolutionary models of the development of civilization and applied them to their interpretation of ancient economic practices. These historians assumed that the earliest

economic systems reflected egalitarian ideas. As society became more complex, temples and religious organizations took over as the economic organizers, eventually to be supplanted by political authorities (such as kings or governments). This type of evolutionary framework was appealing to early historians since it was simple to understand and easily fit the evidence at hand. Now, however, most historians find this framework too simplistic. Indeed, the more evidence that is found, the more difficult it is to reconcile this evidence with the earlier evolutionary interpretations.

Furthermore, historians such as Henri Frankfort and Anton Deimel had made a significant methodological error. They had not taken into account the context of the tablets that they were studying. Upon reconsideration, it became apparent that these early Sumerologists had only been studying tablets that had come from ancient temples. It was no surprise then that temples had seemed to have been at the center of the economy; of course, the majority of economic records that a temple would have kept would have been about its own economic affairs. These Sumerologists, not recognizing that the tablets that they had read had only come from temples (as opposed to palaces or domestic residences), had created a reconstruction of an economy with the temple at the center.

As archaeologists uncovered more ancient tablets from a variety of settings, it became even more apparent that the models of temple economies had been based on this faulty logic. Texts from other types of buildings, especially palaces and houses, contained similar types of economic information. Each of these archives held information relevant to the particular institution that housed the archive. Thus, palace archives contained information regarding palace economic affairs, domestic households contained economic information about individual families, and temple archives contained information about temple economic activities. None of these distinct types of structures suggested that any one agency centrally planned the economy in Sumer. The reconstruction of an ancient economy controlled by a temple and its priests was proved to be unfounded. Therefore, rather than considering temples to be the dominant economic organizations

THE MESOPOTAMIAN RATION SYSTEM

Ignace Gelb has noticed that there are some elements of temple redistribution that are standard from site to site across time. The core of what Gelb refers to as the Mesopotamian Ration System involves the standardized distribution of grain, wool, and oil. Grain was distributed to people monthly, wool was distributed to people randomly, and oil was distributed sporadically. These patterns perhaps reflect logical seasonal harvests and the necessity of publicly storing agricultural products. Gelb considered other goods (for example, fish and dairy products) to be supplementary and did not identify any overarching patterns. While nobody agrees exactly on who the recipients of these rations were, it is likely that they were people who worked for the temple and not the entire populace of the city, as earlier historians and archaeologists had surmised.

Economic Temples, Not Temple Economies

Many Mesopotamian temples seemed to have operated much like large, wealthy Mesopotamian

households. These temples did not simply perform religious roles within the community and on the community's behalf but instead operated manufacturing and production activities similar in scope to other households. Temples owned land that temple personnel farmed directly or rented out to others to farm instead. Temples had their own flocks that could be managed by temple personnel. Although the occasional animal may have been selected from the temple flocks for feasts or sacrifices, mostly the temples used the donations or forced tithes of others in these situations, leaving the temple flocks for the temple personnel's own subsistence. Temples also seemed to have manufactured textiles and engaged in any number of other economic activities rooted in the subsistence practices of daily life.

Richard Zettler has studied the economic activities of the temple of the goddess Inanna (also known as Ishtar) at the site of Nippur during the Ur III period (ca. 2112–2004 BCE). He

THE TEMPLE COMPLEXES AT URUK

The ancient city of Uruk, the supposed home of the legendary Gilgamesh, held many religious complexes. These complexes were used for hundreds of years; when an architectural feature got too old or went out of fashion, ancient builders would simply level out the building and build a new one directly over it. German archaeologists have excavated some of these complexes, reconstructing past temple practices and demonstrating the economic cost of keeping up the temples. Perhaps the most important of these complexes (for the Sumerians and for modern scholars) is the E-anna complex, where some of the earliest Sumerian tablets have been found. This temple precinct was one location of the worship of the goddess Inanna (later known as Ishtar). Earlier than this precinct was the Anu Temple precinct (devoted to the sky god Anu). Here, the best preserved of these temples (also known as the White Temple) contained an offering table and an altar. Perhaps sacrificed here centuries ago were the remains of a leopard and a young lion. The prominence, wealth, and sheer number of these temple complexes at Uruk demonstrate that temples certainly played a prominent role in the economic lives of ancient

Elaborate mosaics adorn walls of the temple of the goddess Inanna (Ishtar) at Uruk, around 3000 BCE. (Erich Lessing/Art Resource, NY)

Mesopotamians. Given that people built them, worked in them, and provided offerings in them, these temples need to be recognized as economic entities just as much as religious entities.

—Kevin M. McGeough

found that during this time the Inanna Temple supported a force of workers and dependents numbering between 250 and 300. These people filled a number of economic roles: millers, festival workers, singers, guards, courtyard sweepers, craftsmen, agriculturalists, animal husbandry workers, and even military personnel. For the services rendered, these people were paid in rations of barley, wool, and oil. One individual was in charge of administering this entire complex. He represented the temple to the rest of the city and organized the distribution of various products. As payment for these services, this head administrator received a large landholding for his own farming where he could be the sole beneficiary of the profits. By studying the tablets recovered from this temple, Zettler was able to demonstrate that this administrative post remained in the same family for at least four generations.

Based on Zettler's study of the Inanna Temple at Nippur and other similar studies, a more nuanced picture of the role of temples in the Mesopotamian economy has emerged than that of the Temple Economy models. Temples were neither self-sufficient economically nor fully de-

pendent on other institutions. Rather, temples participated in economic activities in relationship to other entities: other temples, private houses, and palaces. Some products were produced by the temple. Other products were acquired by middlemen, probably through the exchange of products that the temple did produce. Income also came from performing various religious roles. Private citizens would pay for certain religious services, and on certain festival days, private individuals would have been required to bring certain goods to the temple. The priests would live off of the altar by consuming food that had been originally offered to the deity.

■ Introduction: Currencies, Trading Media, and the Problem of Money

Coins were not invented during this period (4000–1000 BCE), yet trade was an extremely important component of economic life throughout most of the inhabited world. Money, in the sense used here, refers to an abstract (and nearly arbitrary) unit of wealth that is legitimated with a particular value through the backing of the state. In other words, money works since a recognized state decrees that an arbitrary object represents a specific value, and everyone agrees to "play along." Without money per se, the exchange of goods is much more complex because both the buyer and seller have to have something that the other party wants—in fact, both parties are better thought of as buyers—and they must both also agree on the value of

each other's trade goods. Similarly, the storage of wealth is much more difficult; without a bank to deposit money in, the ancient person would have had to stockpile goods, hoping that he or she had enough storage space to keep the object and that the objects would not go bad (so they could not be food products) and that he or she would be able to find a trader for the goods at a later date. Eventually, this system (or lack thereof) was found to be too unwieldy, and alternative systems emerged to help facilitate exchange and wealth storage.

Prior to the invention of money, different regions used different types of objects as currencies to help facilitate trade. These types of objects arose from the ad hoc activities of traders,

as opposed to being formally invested with value by a state body (although the Near East, the Indus Valley, and ancient China all seem to have measurement standards that were decreed as such by the state). The types of goods used as trading media tended to have some sort of intrinsic value (such as silver or amber) and were relatively rare. If an object was too common and could readily be found, then its use as a trading media would have led to rapid inflation, as the market was flooded with currency. The trading media also had to be semiportable over space and time: it had to be able to be easily (and inexpensively) transported and could not spoil (so food products could not be used). Labor, which could be exchanged in some situations, would not work directly as a trading media. However, with the advent of credit, an individual could pledge future service in exchange for the receipt of goods in the present, and thus a form of labor-credit developed as one of the most important tools for the accumulation of wealth.

—Kevin M. McGeough

Using Weights and Measurements in Trade

Weights and measurements are key tools for the facilitation of exchange. The use of weights allows buyers to know the exact quantity they are purchasing and helps determine abstract equivalents in other goods (essentially prices). Yet for a weight system to be useful, it must be consistent and agreed upon. One has to be able to trust that the weights being used correspond to standard abstract value or else there is no point in weighing the goods. In Egypt, Syria-Palestine, Mesopotamia, and India from 4000 BCE to 1000 BCE, weights were extremely common tools used for the exchange of goods.

In the ancient Near East, legislation in various cities governed the standardization of weights. A tablet found at the site of Ugarit (on the coast of Syria) lists the equivalences of measurement systems from different cities, indicating that this standardization varied from region to region even though the metrological language was consistent throughout the Near East. Mesopotamian legal codes contain rules about the standardization of weights, suggesting harsh penalties for

those who use fraudulent weights in a business transaction. In the Code of Hammurabi, it is stated that prices charged for goods must be the same, whether paid for in measures of silver or measures of grain, thus demonstrating that there was a scale of prices based on the weights of various commodities.

At Syro-Palestinian and Indus Valley sites, weights are found in the greatest frequency in city gateways. This, along with textual evidence from Mesopotamia and the Bible, suggests that the city gate is where one would go to conduct business transactions. The weights in city gates may also reflect taxation on imports and exports. Weights and measures are also found in personal homes, suggesting that many people may have had their own set of weights, perhaps in order to check the weights of those with whom they traded.

The system of weights used in the Indus Valley (the Harappan civilization) was completely different from that used in the Near East. It is still used today in some markets in India and Pakistan. The base weight of the system was the *gunja*, which is a small black and red seed. The next weight is double the weight of one *gunja*. The next weight doubles again, as does the next and the next after that. At a certain point, the system shifts to a decimal-based system, and the weights increase in size at a set rate.

ANCIENT WEIGHTS, ANCIENT ARTISTRY

Many of the weights recovered from archaeological sites appear to be valuable pieces of art themselves, not just tools to be used in financial transactions. Often these weights are carved from exotic types of stone (which may have been quite expensive). Stone carving was time-consuming and difficult. The manufacture of accurate stone weights would have been even more difficult given the necessity of carving the weight to the exact size specifications. Elaborate weights that have been recovered were shaped like birds (especially ducks), lions, cattle, bulls' heads, hippos, and other animals. These would have required even more difficult mathematical calculations in their production to produce the correct proportions in a nonstandard form.

—Kevin M. McGeough

What is truly remarkable about this system is that it remained in use unchanged for 700 years, throughout the Indus Valley. Although there is no evidence for a centralized state-level leadership, over this vast space and over a long period of time this very specific system remained the standard. Archaeologists have found weight sets at every Harappan site. The most common types are cubical weights made out of chert. The largest cubical weights have only been found at the larger sites. Some spheroid weights (of measures in the same system), made of jasper or agate, have also been found.

—Kevin M. McGeough

Cubical weights in graduated sizes. These weights conform to the standard Harappan binary weight system that was used in all of the settlements. The smallest weight in this series is 0.856 grams and the most common weight is approximately 13.7 grams, which is in the 16th ratio. In the large weights the system goes to a decimal increase where the largest weight is 100 times the weight of the 16th ratio in the binary system. These weights were found in recent excavations at Harappa and may have been used for controlling trade and possibly for collecting taxes. (J. M. Kenoyer, Courtesy Department of Archaeology and Museums, Government of Pakistan)

Obsidian Trade

Among the earliest examples in antiquity of large-scale long-distance exchange is the trade in Near Eastern obsidian. Obsidian is a type of volcanic glass produced when certain types of lava cool rapidly, such as by flowing into a body of water. Obsidian varies in color, usually from dark green to black depending on the presence of impurities in the glass. Obsidian was highly valued in some cultures that used lithic tools since it can be fractured to produce an extremely sharp edge. Obsidian is still used today in ophthalmic and cardiac surgery, where obsidian blades have a cutting edge much sharper than steel surgical scalpels. Obsidian sources worldwide are very limited in scope and are relatively easily identified through trace element chemical analyses, such as neutron activation analysis and X-ray fluorescence. Obsidian hydration dating even permits absolute or relative dating of a sample by examining the degree of hydration, which corresponds to how long it has been since an artisan exposed the obsidian surface. This makes obsidian an excellent medium for the study of long-distance trade in antiquity.

The main sources for obsidian in the ancient Near East were in the Cycladic Islands off Greece and in central and eastern Anatolia in what is now modern Turkey. Extensive studies have been made of the obsidian sources in Anatolia, and this data has been matched with finds made throughout the Near East of obsidian fragments in early archaeological contexts. For instance, obsidian from Pre-Pottery Neolithic A period (ca. 8000 BCE) sites in Israel and Syria was shown to come from more than 600 miles (1,000 kilometers) away in central Anatolia. This is remarkable given that no domesticated pack animals such as donkeys or camels yet existed. It is likely that this rare material was bartered for equally rare local commodities from the Levant such as bitumen from the Dead Sea or exotic shells from the Red Sea coast.

Since much larger amounts of obsidian were found at the main centers such as Jericho than at outlying sites, it would seem that there was an organized trade network involving these main centers in the Levant with similar such centers in central Anatolia, such as Çatal Hüyük. It is

possible that some of the impetus for the development of such early centers was the control of long-distance trade.

In some cases the trade was in small worked fragments of obsidian. However, in at least one known case from the site of Kabri in Israel, a huge obsidian core has been found, suggesting that in at least some cases whole blocks of obsidian were shipped long distances. The scale of the trade network as reconstructed was immense for its day. Anatolian obsidian was traded throughout the Levant and Mesopotamia and has been found as far south as Beidha in Jordan and as far east as Hassuna in modern Iraq. Anatolian obsidian has also been found on Cyprus, which would have required a boat trip of over 40 miles (70 kilometers) in addition to any land travel to the source. The long-distance trade in this rare commodity continued through the subsequent Pottery Neolithic period, Chalcolithic period, and Early Bronze Age. Analysis of the finds shows that over time, the obsidian comes not only from central Anatolia but also from sites as far east in Turkey as Nemrut Dag.

Amber Trade in Europe

Amber is found in archaeological contexts throughout Europe in Bronze Age levels. Since amber is found primarily along the shores of the Baltic Sea and in parts of eastern England, it is safely assumed that the spread of amber to other areas indicates extensive trade networks

THE SITE OF FRATTESINA

The site of Frattesina, located near the mouth of the Po River in what is now Italy, was one of the major centers of bead production in Bronze Age Europe. Numerous types of materials including bone, ivory, horn, amber, and glass were worked by the craftspeople living at this site. While the glass was manufactured locally, other types of materials (especially amber) were transported to the site in their raw form along with other trade goods, such as ostrich shells and Greek pottery. Amber beads in the styles manufactured at Frattesina have been found throughout Italy and Greece, although the highest concentration has been along the shores of the Adriatic Sea. The people of Bronze Age Frattesina manufactured beads out of a variety of imported raw materials and then exported those beads in exchange for either more raw materials or other trade goods. The direct extent of the trade network may not have been much farther than beyond Italy and Greece. Indirectly, the site of Frattesina had contacts with locations as far away as Scandinavia.

—Kevin M. McGeough

throughout Europe. In particular, amber has been identified as having been used by Bronze Age Europeans in Mycenaean Greece, the Po Valley in Italy, central Europe, and Brittany in France. All of these regions are areas where amber was not naturally deposited. Scholars debate whether these trade routes were by land or by sea. While most agree that a significant component of this trade must have been overland, the lack of amber finds in the Alps as well as the appearance of English amber on the continent suggest that at least some amber was transported by sea. Working of the amber into its final forms took place in the regions to which it was traded.

Amber is the fossilized remnant of tree sap/resin. It was used primarily for personal adornment in Bronze Age Europe, although religious or symbolic uses cannot be ruled out. In finished form, most amber products are beads or spacers for jewelry (especially necklaces and bracelets). Pendants were also formed out of amber. The

styles of the beads varied from region to region, but some patterns of bead exchange have been identified by archaeologists through the study of the spatial relationships of the various types of amber beads.

Archaeologists do not have direct evidence for what the amber would have been traded for, but they can make some good educated guesses. Bronze Age Scandinavia was a center for elaborate metallurgy, yet the region was completely bereft of natural deposits of the ores needed to manufacture metal. Perhaps amber was traded with the southern regions in exchange for metal ores. Finished products were also imported, including axes from Ireland and daggers associated with the Unetice culture. Animal furs may also have been traded; since these kinds of materials do not survive well in the archaeological record, it is not surprising that there is no evidence for this trade.

Cacao as "Money"

Chocolate was considered the food of the gods by the ancient cultures of Mesoamerica. It was served frothed mixed with a bewildering array of chilis, nectars, and spices that would scarcely tempt a modern palate. Because the chocolate drink was so highly prized, the beans (actually seeds) of the chocolate tree, *Theobroma cacao*, were valuable. They were used as a kind of currency in the pre-money eras of Mesoamerica. Money really did grow on trees!

Prior to the introduction of currency into Mesoamerica by the Spanish, products were bartered. The relative value of each product was determined through a negotiation process. The seller tried to set a high price for this product, while the buyer was determined to trade as little as possible. Marketplaces were scenes of intense negotiations as each player tried to make the

other raise or lower the price of the product. As negotiations proceeded, each attribute of the product was evaluated. In the case of cacao, attributes include size, origin, weight, wholeness, color, shape, and dryness. Each of these attributes could change the price. Small beans gave less chocolate per bean, so their value was lower. Different trees gave slightly different flavors, so the origin of the beans had to be established, etc. Once the value was established, then the trade took place.

Cacao beans were also required as tribute. Kings required certain quantities of the beans from their subjects twice a year. Tribute bundles from Classic Maya art are explicitly labeled as *kakaw* along with their quantities. Tribute cacao beans were used in the palace for the king and also were stored or bartered for other services. Gonzalo Fernández de Oviedo y Valdés wrote in 1535 that dried cacao seeds, which he called *almendras*, were used like gold coins. A slave could be bought for 100 dried seeds, a rabbit could be bought for 10 seeds, and a prostitute could be hired for 8–10 seeds.

Mesoamerican markets traded by quantity rather than weight. However, in the case of small objects such as beans and cacao, there were standard quantities traded by bag and known varieties. Yet the market was always a dangerous place for the uninitiated. Friar Bernardino de Sahagún noted around 1580 that there were two types of "Cacahuateros," or chocolate merchants (Book X:XVIII). The good merchants sold beans by variety, the high-quality beans apart from the lesser varieties. The bad merchants put a few good beans on top of the lesser varieties and sold them as top quality. The good merchant sold fat beans, while the bad merchant sold beans that were soaked in water so that they looked like fat beans. (Sahagún lists other marketing practices of both good and bad cacao salesmen.) Thus, merchants were evaluated on their produce and sales tactics because cacao was a very valuable form of currency in an age prior to currency.

Hoard

One of the most puzzling features of Bronze Age Europe is the prominence of hoards of metal objects. Given how valuable metal objects must have been in European society at this time, it is difficult to understand why so much of this material was placed/discarded in the ground. The types of objects most often found in Bronze Age hoards are weapons, pieces of metal armor, metal tools, jewelry, utensils (especially cups and bowls), raw materials (such as ingots), and manufacturing equipment.

Technically, a hoard must include more than one object (although there is no maximum amount of objects that can make up a hoard) and must not be found in a domestic or funerary context. A hoard can be any combination of types of objects, although for Bronze Age Europe hoards primarily consist of metal objects. Sometimes the hoards include unfinished ingots of metal, in other cases they include elaborate crafted pieces of art, and in still other instances used metal tools are included in the mix. Sometimes the hoards consist of only one type of object, while at other times a variety of types of objects are inhumed together.

Anthony Harding has identified four types of hoards that reflect four different types of social contexts for the practice of hoarding: founders' hoards, traders' hoards, personal/treasure hoards, and votive hoards. Founders' hoards contain broken or uncast equipment. These types of hoards were left by itinerant metalsmiths who, rather than carrying heavy metal production equipment and raw materials from town to town, simply buried it in secret locations. When the smith returned to the town or region, he would simply dig up his buried equipment. Traders' hoards reflect a similar economic system, but the objects found in these hoards are finished objects, ready to be traded. Personal/treasure hoards consist of a variety of types of objects (usually with no discernible pattern). These hoards may have been buried in advance of an enemy attack to prevent

THE HAJDÚSÁMSON HOARD

In 1907 an unusual discovery was made in a drainage works in northeastern Hungary. Around 1800 BCE, Bronze Age individuals had left what was clearly a votive hoard in the sandy earth. A sword was set down with its blade pointing directly north. After this, Bronze Age people had laid 12 shaft-hole axes (called so because the hole for the handle was cast directly into the bronze) across the sword, with the ax blades facing west. These pieces were clearly very expensive. Each was individually cast; none were mass-produced. The sword and three of the axes had an intricate c-scroll design incised into them, typical of the design schemes on metal objects produced in the Carpathians. This votive offering represented a significant investment of wealth by the Bronze Age individual, indicating the importance of this kind of offering to Bronze Age people.

—Kevin M. McGeough

soldiers from carting off the valuables as booty, or they may have been buried for everyday security (in the absence of locks or other means of securing valuables in a Bronze Age village). Votive hoards are also made up of finished metal objects, but in these cases the contexts (especially the placement of the materials within the hoard) indicate some ritual, ceremonial, and/or symbolic motivation for the interment of the material.

Credit and Debt in the Ancient Near East

Credit and debt were two of the most important means of structuring financial relationships in the ancient Near East. It is likely that credit

➤ A RECORD OF DEBTS FROM RAS IBN HANI

Located on the Syrian coast and inhabited during the Bronze Age, Ras ibn Hani was a small town located near the large city of Ugarit. Numerous economic texts have been recovered from Ras ibn Hani, including tablets that record debts incurred by individuals. One individual named *mnny* loaned out a significant quantity of silver. The tablet reads as follows:

“Record of the silver of *mnny*.

Seventy shekels of silver debited upon *antrn* the son of *ymr*.

Forty shekels of silver debited upon *tmrtn* son of *urmy*.

Forty shekels of silver debited upon *bnrl* son of *krwn*.

Sixty shekels of silver” (translation by author).

This is all the information that is preserved; the tablet does not say why *mnny* made these loans or provide any other information about the conditions of the loans, even what was expected to be repaid. This is the kind of laconic text that economic historians are forced to work with in order to reconstruct ancient financial practices!

—Kevin M. McGeough

worked similarly in other parts of the ancient world, such as China or the Indus Valley, but given the lack of preserved economic texts, it is impossible to be certain. Credit is an agreement that is made when the debtor receives something of value from the lender in the present and promises to repay the lender in the future. The benefit to the debtor is the receipt of valuable goods in the present without having to supply anything in the present. The benefit to the lender varies. If interest is charged and the lender does not actually require the goods at the present time, then a profit has been gained. In ancient times the benefit may also have been a payment in labor (as opposed to a return of the actual loaned good). For example, an owner of a large agricultural estate would only need laborers at certain times of the year, so providing goods to a laborer at one point in the year with promise of future labor may have been valuable. Likewise, the lender may have wanted future payment in a

product that eventually goes bad, such as food products. By giving an individual seed or agricultural equipment during one season with the promise of future payment from the agricultural yield, the lender can count on a delivery of food later in the year. Since there was no money per se in the period from 4000 to 1000 BCE, debt and credit were used to help facilitate exchange since it allowed two individuals to fulfill each other's economic wants more easily.

In the absence of a monetary economy, credit also allows for the storage of wealth. In Mesopotamia, wealthy individuals gained influence by accumulating debtors. Cuneiform tablets bearing lists of debtors and amounts owed have been recovered from private homes, temples, and palaces. For a person or organization that produces an agricultural surplus that cannot readily be stored (more than can be consumed by the person or organization), the person or institution can convert that surplus into wealth. Poorer individuals or individuals who did not engage in agriculture were able to gain valuable food in exchange for future work or payment. Thus, an organization that had many debtors had converted present wealth into future wealth through debt agreements.

When interest was charged, debtors could be transformed into virtual slaves, never being able to fully repay their principle debt. This was especially common when agricultural workers paid for agricultural equipment or seed with the yield from their crop. Once this cycle began, the farmer would not be able to produce enough of a surplus to pay for necessary equipment in the next agricultural year (let alone any owed taxes) and thus would have to enter into a similar agreement. Eventually the leftover yield would be insufficient for the family's subsistence needs, and one of the members of the family would have to enter into a relationship of debt slavery with the creditor. This was likely a widespread problem in Mesopotamia, as studies of ancient legal literature suggest. For example, the Edict of King Ammisaduqa of Babylon, enacted around 1640 BCE, canceled debts throughout the kingdom and allowed debt slaves to regain their freedom. This kind of decree is also found in the Old Testament; for example, in Leviticus 25 a Jubilee

Year is legislated to occur every 50 years in which all debts are canceled.

In ancient Mesopotamia, numerous laws governed debt and credit relationships, although they varied through time and from city to city. According to some legal codes, the creditor was limited in what he or she could distraint (seize) from the debtor for nonpayment. Agricultural goods and equipment (or other products that could interfere with the creditor's ability to earn a living or subsist) were typically exempt from seizure. In some cities, repayment of interest followed an established scale, and the creditor was compelled to accept payment in goods that were not necessarily originally agreed upon as forms of repayment. Laws also existed that governed the treatment of individuals pledged to the creditor as debt slaves in lieu of payment. Depending on the status of the slave, the creditor faced different punishments for mistreatment of the slave

and was often forbidden from selling the slave to someone else.

■ Introduction: The Old Assyrian Trade Network

One of the best-understood ancient trade networks is the Old Assyrian network that flourished from about 2000 to 1776 BCE. Trading families in the ancient city of Assur (located in Assyria in northern Mesopotamia) took advantage of Assur's strategic location between north-south and east-west trade routes and organized long-distance trade ventures that profited off of differences in economic landscape between these regions. By bringing goods that had been produced in southern Mesopotamia (such as textiles) and raw materials from the east (such as tin from Afghanistan) to Anatolia, which was rich in other mineral resources, the merchants of Assyria made a tidy profit. No doubt similar commercial ventures existed in other locations in the ancient world, but what makes this situation so unique is the wealth of evidence that has survived documenting ancient economic life and commercial practices. What follows are discussions of the organization of this early commercial network and of the partic-

ular historical situation in which this network emerged.

—Kevin M. McGeough

The Old Assyrian Trade Network—Tin and Textiles for Silver

Beginning around 2000 BCE (middle chronology) and continuing beyond the death of Shamshi-Adad (1776 BCE), private merchants from the town of Assur (present-day Qala'at Sherqat) conducted a profitable trade in tin and textiles with the politically diverse cities of the central Anatolian plain. While the early developments are difficult to trace, business records (in excess of 20,000 texts) provide a detailed picture of commerce during 1900–1845 BCE. Merchants packed and sent their wares by donkey in large caravans along the 745-mile (1,200-kilometer) route across the Syrian steppe, the Euphrates, and the Taurus Mountains to the main terminus of the trade

➤ TIN AND TEXTILES

“‘You only love money! . . . Come back to Assur!’ writes Shīmat-Assur to her husband Imdilum. It took close attention, capital, good representatives, and long stays in Anatolia to become a wealthy merchant and some wives clearly begrudged their husbands’ absence and perhaps also the second houses and wives in Kanesh. Tellingly, Shīmat-Assur also complained sharply to her husband because he delayed her own profits. Imdilum, and Shīmat-Assur as well, benefited greatly from the favorable price difference in tin and textiles between Assur and Kanesh, though other merchants, like Assur-nādā whose father’s small coffers and poor reputation, found success more elusive” (translation by author).

route at Kanesh (present-day Kültepe), where they converted their wares into silver in any number of ways. Later, it is evident that trade during the reign of Shamshi-Adad was different in nature, less lucrative and smaller in volume due in part to political consolidation on the Anatolian plateau and increasing security problems en route.

To further the operation of private trade, a host of institutions were necessary, both public and private. Assyrian merchants developed business procedures to facilitate shipping, representation, agency, credit, and liquidity of funds. This included caravan procedures, partnerships, joint-capital investments, accounts at the colony office, and exchangeable debt notes. Family in part provided a framework for partnership, cooperation, and contacts. Some merchants lived most of their lives in one Anatolian city or another, doing business for themselves and on behalf of associates who either lived in Assur, specialized in shipping, or frequented a different area of the plateau.

The semirepresentational state, itself benefiting enormously by taxing the trade, served the interests of elite investors manifest in the decision-making powers of the city assembly. Although the king’s position was hereditary, held for life, and involved a relationship with the god of the city, he shared power with the city assembly, divided into the “big” and “small” men, whose decisions the king carried out in an executive role. The state negotiated trade agreements with the cities of the Anatolian plain, regulating taxes on imported goods and outlawing competition, and authorized organizations to represent the state in Anatolia; they possibly also regulated merchant licensing. These organizations, the *karum* (located in larger cities) or *wabartum* office, also regulated the legal affairs of the merchants abroad.

The *karum* (or port) at Kanesh, outside the city walls, included houses inhabited by native Anatolians alongside houses that the merchants purchased, where in strong rooms they stored their wares and important documents. Textual documentation derives almost entirely from these houses, of which roughly five dozen have been uncovered; only a handful have been found inside the palace or within the city walls. Anitta controlled this palace during the Shamshi-Adad phase.

The Assyrian export trade to Anatolia was just one part of a much larger economic exchange network. Tin, an essential ingredient in the contemporary bronze, lapis lazuli, and carnelian came from as far east as the Turan Mountains via the Iranian plateau and Susa. Most woolen textiles were institutionally produced in other Mesopotamian cities and were acquired on the market, while small numbers of textiles were produced for export in Assur by merchants’ wives. Copper, though readily available in Anatolia, was not imported into Assur, as it was available more cheaply from Oman and possibly mines to the north of Assur.

The Karum System

The Anatolian town of Kanesh (modern Kültepe) was favorably located at the intersection of several major routes north-south and east-west, the latter connecting Anatolia with Mesopotamia. Archives of clay tablets baked and thus preserved when Kanesh was destroyed by fire around 1820 BCE (end of period II) and again around 1740 (end of period Ib) have yielded a fascinating picture of mercantile activities here. For some three generations in the period II, merchants from the

northern Mesopotamian city of Assur operated a trading colony (*karum*) within the walls of Kanesh's lower town. A ground-floor room within their well-appointed houses was reserved for use as a sealed strongroom in which both valuables and their business archives were kept. Their houses and domestic objects were generally indistinguishable from those of local people, so we would have had no way of identifying them as foreigners were it not for their abandoned archives. Other merchants from cities in the Levant, including Ebla, also traded in the town.

The *karum* was established around 1880 BCE to obtain Anatolian silver and, to a lesser extent, gold in exchange for tin (*annakum*) and textiles brought from the merchants' home city of Assur. Some of the textiles were made by their wives and daughters, but most were the top-quality products of Babylonia (perhaps imported through the Assyrian colony in Sippar). The tin also came

► THE MESOPOTAMIAN QUEST FOR METALS

Given the relative paucity of mineral resources in Mesopotamia, copper and other metals had to be obtained from other lands, either through conquest or trade. Tin was probably traded from Afghanistan or eastern Iran, and during the fourth and third millennia, copper and gold also came mainly from the east, copper from the Oman peninsula and gold from the Indus civilization and beyond. Other copper sources became important in the second millennium, including Alashiya (Cyprus); copper from here was recorded at Mari. Another important source for Mesopotamia was eastern Anatolia. A text written much later than the events it recounts, *King of Battle*, claims that Sargon of Akkad led a military expedition to aid merchants suffering persecution in the Anatolian city of Burushkhanda, although this story probably had little factual basis. However, an inscription of Sargon's grandson, Naram-Sin, at Pir-Hussein in southeast Anatolia confirms Akkadian activity in the general region. Excavations in the central Taurus revealed mines at Kestel and metal processing at nearby Goltepe, suggesting that tin was produced here during the third millennium. The Taurus was rich in other metals too—copper, gold, silver, lead, and antimony—and had been known since the time of Sargon as the Silver Mountain. Lead isotope analysis of silver goods from Mesopotamian sites over a long period has demonstrated that all those tested came from the Taurus sources.

—Jane R. McIntosh

from farther afield, probably traded from Afghanistan across the Iranian plateau. Elam was the transit source of tin imported some years later by Mari and Sippar.

The heads of the trading houses resided in Assur, many of them local aristocrats who sat on the councils that advised the king. Here too dwelt the womenfolk of the merchant families, raising their children and making textiles but often also dealing with the Assur end of the business for their husbands in Kanesh. The trade was strictly regulated by the authorities who, for example, prohibited trade in Anatolian textiles and luxury goods. A tax of 1/120th of the value of the exports was payable to the palace when an expedition set out.

A council of senior family members oversaw the affairs of the karum at Kanesh, extracting a levy from incoming caravans to pay for its day-to-day running. The king of Kanesh received a tax of 2/65th of each shipment of tin and a fifth of the textiles and could purchase 10 percent more at a favorable rate. Then there were the expenses of the caravans carrying the goods, including local taxes in the areas they passed through. Nevertheless, the value differentials between the regions (tin, for example, being valued at more than twice as much silver in Anatolia as it was in Assur) made the exercise highly lucrative, and a profit of 100 percent was not unusual. Expeditions were financed partly out of profits from earlier trading and partly by investments. Individuals could add their own goods to a consignment. Partnerships of a number of merchants could put up capital (*naruqqam*), which was entrusted to a merchant for a long-term trading venture. Each investor bought shares costing 8 minas (4 kilograms, or about 130 troy ounces) of silver each and was guaranteed a return of 100 percent at the end of the term (in one recorded case this was fixed at 12 years).

Kanesh was the head office of Assur's operations in Anatolia, with substantial branch karums or smaller offices (*wabartum*) in other towns, including Hattusas, the future Hittite capital, and Purushhattum (Burushkhanda, modern Acem Hoyuk). Some facilitated the trade in silver, while others dealt locally in less-valuable trade goods such as copper or wool, the profits eventually being converted into silver. With care, using a smuggler's path, merchants could also engage in tax evasion or illegal trade, for example in iron, still a rare and prestigious material whose acquisition was monopolized by the Assur authorities. After one of their merchants had been arrested for smuggling, an Assur house wrote to their karum representative advising him to leave their iron in a safehouse en route, pending further consultation.

The small donkey caravans from Assur were led by experienced carriers along several established routes. Each donkey carried two packs of around 65 minas (ca. 72 pounds or 32.5 kilograms) of tin and a few textiles, making a total weight of around 180 minas (198 pounds or 90 kilograms); sometimes the amounts varied, or

textiles alone made up the saleable part of a load. In addition, the donkeys carried around 10 minas of tin to pay the incidental expenses of the 6 to 12-week-long journey (about 745 miles or 1,200 kilometers) on foot. On arrival in Kanesh the donkeys were probably sold, since the far smaller bulk of silver could be borne home to Assur by the carriers themselves.

Around 1820 Kanesh was sacked, probably by the king of Hattusas, and the karum folded. It was revived, though as a much smaller and more circumscribed operation, when Shamshi-Adad ruled northern Mesopotamia, but it did not outlast his dynasty's collapse.

Prices in Old Assyrian Times

The Old Assyrian merchant trade functioned on a market basis where supply and demand were major factors in determining prices of goods moving through an interregional network. While

➤ ASSYRIAN MERCHANT COMPLAINTS

Assyrian merchants frequently expressed frustration about market and price in their correspondence. "I didn't buy Akkadian textiles because the price is unfavorable. . . . I will buy and send you tin unless the price of Akkadian textiles has leveled within ten days." Supply was often the problem. Assur-nādā warns an associate, "Silver is difficult [to obtain], don't expect much silver, the commerce is poor." Another merchant dismisses excuses for lack of silver from defaulting debtors: "When I stayed there, they told me, 'There is nothing to trade on the market.' But now I hear there is plenty to trade on the market."

in certain circumstances tin (road tax on the way to Anatolia) and copper (road taxes in Anatolia) were used as bases of exchange, silver was the standard (*valuta*) of the day, and Assyrian merchants normally expressed the value of their commodities in terms of silver. The favorable rate of exchange for silver, cheaper in Anatolia due to its great supply, was perhaps the single greatest force fueling the trade between Assur and the cities of the Anatolian plain. Differences in supply between markets within Anatolia meant that the Assyrians were quick in developing systems to maximize their gain. In Kanesh they exchanged their tin and textiles for wool, trucked it north to the copper mine region, and transported obtained copper west to Purushattum to exchange for silver. Gold was also acquired in Anatolia, but an Assyrian law mandated that gold acquired in Anatolia be shipped back to Assur and converted into silver, the gold being hoarded by the state.

The long distances of the trade, demanding that the goods garner favorable exchanges between Assur and Anatolia, dictated that copper, despite its abundance in Anatolia, was not shipped to Mesopotamia. Carnelian and lapis lazuli, coming from the same direction east as

the tin, were items of sufficient value and scarcity to be included on the trip to Anatolia when available. Tin, essential for making tin bronze, was an obvious choice for export to Anatolia, but the seemingly inexhaustible demand for high-quality woolen textiles is remarkable. In fact, so attractive was the textile trade to the Assyrian merchants that the Assyrian state mandated that a certain percentage of their shipments consist of tin. Their correspondence reflected the merchant's sensitivity to price. One merchant says that tin was too expensive (16:1 tin to silver) and that purchase was deferred until the rate improved (15:1 or 14:1). Likewise, some merchants stockpiled goods in Anatolia, waiting to sell until a supply problem drove prices up. Tin was normally sold between 6:1 and 8:1. Woolen textiles varied greatly. The *kutanum* textile normally cost 4–5 shekels of silver in Assur and was sold in Anatolia for a wide range of prices (11–40 shekels) depending on the urgency to liquidate, access to trustworthy retailers, quality of product, and immediate demand and supply.

Not only goods but also capital and services were priced. A rough division of labor in the merchant system meant that those who had capital lent it out, while merchants paid a price for access to that capital. The state exercised some regulation of these prices, declaring a standard interest rate on loans between two merchants, although friends loaned on (only) slightly better conditions. A disgruntled creditor could take out a loan to recoup his capital on a defaulting loan, forcing the debtor to pay double interest (to the original and new creditor). Merchants also had access to long-term options such as the *naruqqu* investment whereby a merchant combined investors' capital with his own small sum to create a working fund with which to do business for a term of normally ten years. The merchant kept one-third of the profits, investors divided another third in periodic installments, and the last third was reinvested in the fund. Investors received an increase in their capital shares at the end of the term. In similar fashion, merchants paid service providers, such as shipping personnel, by giving them interest-free loans with which the shipper would recoup profits in the same manner as the merchant.

Shamshi-Adad's Covetous Eye

Shamshi-Adad was an ambitious and successful ruler who created an extensive kingdom in northern Mesopotamia. His political career is reconstructed from king lists, several royal inscriptions, and hundreds of diplomatic letters from palace archives. Shamshi-Adad reigned for 33 years according to the Assyrian King List, a document that reports the length of reigns for the kings from Assyria. During this time, he successfully united an extensive kingdom in northern Mesopotamia, which exploited the lucrative trade routes running from Iran to southern Turkey and the Mediterranean coast. His kingdom of upper Mesopotamia, however, did not last more than one generation and collapsed soon after he died.

Shamshi-Adad's early career is obscure, but evidence suggests that he was a native of the city of Akkad, one of Mesopotamia's most ancient capitals. He ascended to the throne of his father, Ila-Kabkabu, but after 18 years was forced into exile to the Babylonian court of Hammurabi. After this exile, Shamshi-Adad enacted a series of military operations aimed at gaining control of strategic cities along east-west trade routes. First, he recaptured the city of Ekallatum, on the Tigris River, from which he launched many of these campaigns. From there, his most significant territorial gains were to the west and north, including the cities of Ashur on the Tigris River and Mari on the Euphrates River. These military successes across upper Mesopotamia resulted in his adoption of the royal title "The one who united the land between the Tigris and Euphrates."

Having secured these newly conquered regions, Shamshi-Adad established Shubat-Enlil (Tell Leilan) as his capital city and appointed his two sons as viceroys: Ishme-Dagan, his elder

son, along the Tigris River at the eastern city of Ekallatum, and Yasmah-Adad, a younger son, along the Euphrates River at the western city of Mari. At this time, Shamshi-Adad and his sons advanced their interests through international treaties. For example, Yasmah-Adad married the daughter of the king of Qatna, Ishhi-Adad, and this resulted in close economic ties between the two kingdoms. Shamshi-Adad also negotiated peace with Dadusha, the king of Eshnunna.

Shamshi-Adad's vast kingdom was in almost constant need of military actions to reinforce his authority and to secure trade routes. Therefore, after stabilizing international boundaries and diplomatic relations with neighboring states, Shamshi-Adad and his two sons redirected their military efforts to the east and northeast. Campaigns commenced to Arrapah south of the Lesser Zab and then spread north as far as the city of Nineveh. Subsequently, Shamshi-Adad campaigned to the west, where Larim-Numaha, the king of Aparaha, had instigated a revolt in the region between the upper Euphrates and the Balih rivers. This revolt persisted for months and was quelled only when Ishme-Dagan arrived with 10,000 troops. Having defeated Larim-Numaha, Shamshi-Adad was confronted with further rebellions fomented by Sumu-Epuh, the king of Yamhad. This rebellion targeted east-west trade routes that crossed the upper Habur, near the Tur-Abdin Mountains, and the upper Euphrates at the city of Emar. The unrest persisted for

many months until the king of Yamhad died, which finally allowed Yasmah-Adad to confront the problem through a combination of military action and diplomacy. Shamshi-Adad's final military victory was recorded against the kingdom of Malgium, located east of Babylon along the Tigris. It was not long after this, however, that his kingdom of Upper Mesopotamia began to crumble. Shamshi-Adad's health failed, and he was no longer able to negotiate the fortunes of his kingdom. Seizing this opportunity, the king of Eshnunna, a former ally, expanded east of the Tigris, while discontented populations throughout the kingdom stirred up unrest and reinstalled local dynastic rulers. Shamshi-Adad's kingdom of upper Mesopotamia did not survive his death (ca. 1776 BCE). As for his sons, Yasmah-Adad was driven from the city of Mari and presumably killed, while Ishme-Dagan retained control of the city of Ekallatum, although his sphere of influence was curtailed to the environs of this city.

■ Introduction: Regional Exchange Networks

Long-distance trade networks connected many parts of the world during the period between 4000 and 1000 BCE. Rarely were these formally organized enterprises. Rather, they emerged on an ad hoc basis and gradually developed formal institutions and infrastructure. As the networks became more formalized, the regions that participated in these networks became more integrated and interdependent, growing to require goods, ideas, and social relationships from other participants in the network.

Exchange networks centered on major nodes, usually cities that were strategically located near seas or along major rivers. Sometimes these major nodes were not geographically well located from a transportation perspective but instead developed in areas of high population density or regions of considerable economic, political, or religious authority. Within any given network there was a hierarchy of nodes. Major centers would exchange with other major centers. Smaller centers in the hinterland of the major

centers would exchange with the nearby larger center. Even smaller centers in the hinterlands of the medium centers would exchange with the medium centers. Thus, whole regions on the margins of an exchange network had indirect access to the goods and ideas that traveled along these routes.

The nodes of ancient exchange networks were connected in many different fashions. Traders could go to different ports and trade directly with the individuals of those cities, or middlemen could facilitate trade by conveying goods between different regions. Some centers acted as a central place where traders from all over the network could gather to exchange goods and ideas. Enclaves of foreign merchants sometimes appeared in a district of a major center, or political emissaries participated in both trade and diplomacy at the whims of foreign rulers. Goods could also be passed “down the line,” moving between adjacent nodes. Thus, exotic objects could move considerable distances without parties at the beginning or end of the line being aware of one another’s existence.

Most of the exchange that took place within these networks was reciprocal; that is, the direct exchange of goods occurred between individuals who knew each other or who had developed an exchange relationship. Credit was less important in these financial situations than in local exchange systems since there was no guarantee that both parties would see each other again and only minimal legal infrastructure existed that could protect parties from different polities. Abstract exchange media (i.e., currency) was not used frequently, given the varied values that goods had in different regions and the difficulties of establishing normative prices across regions. So, parties usually traded directly for goods that were mutually desirable (or that one party knew could be traded elsewhere for a profit).

Eastern Mediterranean Trade

Throughout antiquity, the Mediterranean Sea, known as the Great Sea, has acted as a unifying force for rather than a barrier to the states bordering it. The sea-lanes of antiquity were exploited early on, and the different coastal states enjoyed a lively trade with one another. Evidence for trade between different Mediterranean regions begins in the Neolithic period (sixth millennium BCE). Obsidian, a black glassy stone that was used to make very sharp blades, was imported from Anatolia to the island of Cyprus at this time.

In the Early Bronze Age, around 2400 BCE, Greece and northwestern Anatolia shared several cultural features that showed that these regions were in close contact with one another. The shapes of pottery, metal containers, and jewelry from island sites such as Poliochni and Troy closely resemble one another. A real move forward in interregional relations took place in the Middle Bronze Age. In the Levant, there is an explosion of sites founded on the coast in the Middle Bronze Age. By this time, improvements in shipbuilding allowed the peoples of the Levant to take advantage of their access to other Mediterranean ports. The Levantine states traded with Egypt to their south and to a lesser degree with Anatolia to their north. Regular trade between the Levant and the Aegean world and

Painting of Cretans Bringing Gifts, from the tomb of Rekhmire at Luxor, Egypt, about 1479–1425 BCE. (The Metropolitan Museum of Art/Art Resource, NY)

with the Aegean and Egypt also seems to have increased by this time, although the physical evidence of this trade is sparse. On Crete a few Egyptian scarabs, Mesopotamian seals, and Syrian daggers have been found, and a few examples of Minoan pottery made their way to the Levant and Egypt. Documentary evidence shows, however, that these regions were linked through the demand for tin, an essential ingredient for the forging of bronze. Texts from Mari (present-day Tell Hariri) in Syria show that tin was brought through here from the east and made its way to western ports such as Ugarit. Foreign merchants operating in Ugarit secured tin for transshipment west. In exchange for the tin the Minoans brought textiles, weapons, and pottery, mostly luxury goods.

It is in the Late Bronze Age, roughly 1500–1000 BCE, that all of the eastern Mediterranean states were drawn into a single exchange network, consistently trading with one another. In the early part of the period the Minoan influence was particularly strong, and Minoan artistic styles were copied throughout the eastern Mediterranean. Many of the palaces may even have shared or traded craftsmen. Several Minoan-style frescoes appear at Levantine sites, with the best example found at Tel Avaris in northern Egypt. Much of this trade was controlled by the palaces that had the resources, capital, and ties to secure overseas and land shipments. There is also some evidence for private merchants plying objects overseas at the same time. Overseas shipping linked all of the eastern Mediterranean. By this time, fleets were almost certainly following the sea routes running from Crete to Egypt and then back along the coast of the Levant, the southern shore of Turkey, and back to the Aegean Islands and the Greek mainland.

An archive of letters found at Tell el Amarna in Egypt documents the practice of gift-giving between the royal palaces of the Near East and Egypt. On a semiregular basis the kings of Egypt, Anatolia, Assyria, and Babylonia and possibly also Mycenaean Greece and Cyprus sent each other large shipments of luxury goods as greeting gifts in the fourteenth century BCE. At this time Cyprus played an especially important role, as it seems to have been a major supplier of much of the copper circulating in the Mediter-

➤ MYCENAEAN AND CYPRIOTE POTTERY

Without question the most prized pottery in the Bronze Age eastern Mediterranean world was the painted vessels of Greece and Cyprus. Mycenaean and Cypriot pottery was the most sought-after tableware of the royal courts of the Mediterranean. These were widely traded between the Mediterranean states and are found in surprising numbers at Levantine coastal sites. Both types of pottery, the Mycenaean and the Cypriot, were placed in wealthy tombs and in some sense served as status symbols. The pottery was especially popular in the Late Bronze Age (Cypriot, sixteenth–fifteenth centuries; Mycenaean, fourteenth–thirteenth centuries). The potters on Cyprus were able to achieve very fine thin-walled vessels with a lustrous paint and elegant shapes mimicking metal vases. The light color, decorations, and shapes of Mycenaean pottery made it highly desirable to the Levantine market. The Mycenaean and Cypriot vessels were imported both for the quality of the vessels themselves and also for the products contained within these vessels. Small Mycenaean stirrup jars, for instance, probably held high-quality perfumes. Mycenaean and Cypriot pottery has become an important marker in the archaeological record. When found outside Cyprus and Greece, this pottery helps to establish links between different regions and give rough chronological dates.

—Susan Helft

anean, the other essential ingredient of bronze. A pattern of trade networks for the fourteenth–thirteenth centuries in the eastern Mediterranean is apparent in the textual and archaeological evidence. Cyprus supplied copper to the Aegean centers and to the Near East and Egypt. Egypt traded ivory, ebony wood, and especially gold to the other powers; Greece had silver and pottery, some of which contained expensive perfumes. From the Levant, olive oil and probably wine as well as hippo ivory were important exports, and from the Near East it was textiles. It is unclear exactly who controlled or initiated much of this trade, but the shipping was almost certainly in the hands of Minoans, Mycenaeans, and Canaanites.

Iranian Caravans across the Zagros

From early times, desirable materials such as obsidian had circulated widely in the Near East, and by the fifth millennium BCE, turquoise from central Asia and lapis lazuli from Afghanistan were known in Mesopotamia, Susiana, and other lands thousands of miles from their sources.

During the Uruk period, the Sumerians became more proactive in their trade with their neighbors, establishing trading outposts to control the acquisition of resources, such as that located within the settlement of Hacinebi to obtain Anatolian copper. Sumer was closely involved with Susa and Khuzestan, through which it may have imported copper from Talmessi on the Iranian plateau. By 3000 BCE, copper was being alloyed with tin to produce bronze, making it harder and therefore more useful. Thereafter copper and bronze grew in importance, promoting trade.

The fourth millennium saw organized trade networks developing across the Iranian plateau, where more tenuous links had existed for millennia, with towns growing up at nodes in natural routes across the plateau and at places where desirable resources could be obtained. Shahr-i-

INDUS REGION TRADE ROUTES AND SITES, CIRCA 3,000 BCE

Sokhta in southeastern Iran acted as a break-of-bulk point on the route from the lapis lazuli source area at Badakhshan. Here, raw lapis nodules containing impurities were chipped and cleaned into smaller pieces of pure lapis for more efficient transport. Tepe Yahya to its southwest was located close to a major source of chlorite. Many workshops here made chlorite artifacts, particularly decorated bowls, that were widely exported to various Elamite and Iranian towns, sites in the Gulf, Sumerian cities, and Mohenjodaro in the Indus Valley, a fair illustration of the extent of contemporary trade networks.

A Sumerian literary composition, Enmerkar and the Lord of Aratta, probably set around 2700 BCE, recounts how Enmerkar, king of Uruk, wishing to build a temple to Inanna, employed various strategies to obtain lapis lazuli, silver, and gold from Aratta, a land beyond Anshan and seven mountains. Aratta also worshipped Inanna. Enmerkar at first attempted to bully the king of Aratta by claiming that the goddess preferred Uruk. Threats and demands were made on both sides, and at one stage Enmerkar dispatched donkey loads of grain to Aratta, finally receiving the precious materials. Suggestions that Aratta may have been located in southeastern Iran have been given a boost by the recent discovery of a civilized society on the Halil River in Kerman Province, 124 miles (200 kilometers) north of the mouth of the Gulf. Named Jiroft after the local city, it came to international attention after looters ransacked a large cemetery. The cemetery and associated settlement are still in the early stages of investigation, but material believed to be from here appears to be contemporary with Early Dynastic and Akkadian Mesopotamia and includes a large quantity of chlorite vessels.

In another tale (Gilgamesh and Huwawa) Enmerkar's grandson Gilgamesh and his bosom companion Enkidu undertake an expedition into the mountains, where (by very underhanded means) they slay the demon Huwawa, the guardian of the cedar forest, and ship the trees back to Uruk. Although in later times cedar came from Cedar Mountain (Amanus range) in the Levant, it is possible that this poem refers to the importing of such valued timbers from the Zagros Mountains in the earlier third millennium.

Iran—Between the Persian Gulf and Bactria

Mesopotamia was an important trade partner of Iran's but certainly not the only one. Located between the Persian Gulf and the Caspian Sea, Iran is a natural middleman for the Gulf regions and Bactria (modern Afghanistan and Uzbekistan). Ancient Iranians (known as Elamites) took advantage of this position, trading for goods from these regions to the north and south cheaply and making a substantial profit when trading these goods to the Mesopotamians across the Zagros Mountains.

The most important component of this trade was the tin that the Elamites gained from the Bactrians. As tin is an essential component in the manufacture of bronze, this metal was highly sought after throughout the Near East. Other Bactrian objects were also desired by the Elamites. Stone vessels and statues from this region were found at Susa along with numerous other small items.

Archaeologists have unearthed substantial evidence for Elamite trade relations to the south as well. One of the main trading regions was what is now known as Bahrain but in ancient times was called Dilmun. This small island, across the Persian Gulf from Elam, must have had considerable influence at the Elamite city of Susa. The god Enzag (the chief deity of Dilmun) was venerated at a temple there (or a deity from Susa took the name Enzag). Dilmun stamp seals have been found at Susa as well as locally made imitations of Dilmun iconography. A contract stamped with a seal from Dilmun was found

there. Another contract from Susa records the delivery of 175 *minas* (a unit of measurement) of silver that were brought by “the Dilmunite.”

Oman, also across the Persian Gulf, must have traded goods with Elam. In the Bronze Age, Oman was called Magan. Distinct stone vessels from Magan have been found in Iran. It is presumed that traders were interested in the contents of these vessels, which unfortunately have not been preserved.

—Kevin M. McGeough

➤ TRADE AND TRANSPORTATION IN THE INDUS VALLEY

Clay model cart pulled by oxen from the ancient city of Mohenjo-daro, in present-day Pakistan. (Corbis)

Archaeologists have not unearthed any ancient Harappan vehicles that were used for transporting trade goods. Evidence for this comes from indirect sources: miniature clay models and artistic depictions of vehicles. Over land, traders could have used any of several different styles of two-wheeled carts, undoubtedly pulled by oxen or donkeys. Camels and horses were used in central Asia, but there is no evidence that these animals were used by the Harappans. River craft would have been better suited for long-distance trade; models of flat-bottomed boats have been unearthed. These may have been powered by sail or oar or even by being towed by people walking on the shore, slightly in front of the boat. In order to trade with Oman, the Harappans would have required sea-going vessels as well, but there is little evidence for what these looked like.

Harappan Trade

Trade was extremely important for the ancient Harappans since the Indus Valley was quite limited in mineral and metal resources. The region was quite agriculturally productive, but the many luxury goods that have been retrieved from excavations could not have been produced from materials located on the Indian subcontinent. Gold, however, was quite widely available on the subcontinent in ancient times, and this was one of the major resources that the Harappans exchanged outside of the Indus Valley. There were two primary regions outside of the Indus Valley where the Harappan traders had established active trade networks: Baluchistan to the west and Oman to the south, across the Oman Gulf. There is less clear evidence for trade with Mesopotamia (ancient Iraq) as well.

Baluchistan, located in parts of what are now known as Iran, Afghanistan, and Pakistan, was a source of much mineral wealth. Copper was exceptionally important, and much of the metallurgical production of the Indus Valley was reliant on a predictable stream of copper from Baluchistan. There may have been some copper sources available in the Indus Valley as well, but given the preponderance of copper at Harappan sites, these local resources must have been supplemented by external resources as well. Lapis lazuli, which was highly regarded by the Egyptians and Mesopotamians, came from Afghanistan and thus likely came into the Indus Valley through Baluchistan. There were substantial lead deposits (and by extension other resources associated with lead such as silver) in Afghanistan that may also have been traded to the Harappans. Finished products from Iran (ancient Elam) also made their way to the Indus Valley probably via Baluchistan, although since the Elamites traded with Oman, the middlemen may have been located across the sea.

Trade with Oman must have been extensive as well given how many Indus Valley artifacts have been found in Oman and how many artifacts of the Oman style have been found in the Indus Valley. Oman also had access to significant copper resources, so this may have been one of the principle imports to the Indus Valley. Precious stone would also have been imported.

No finished Mesopotamian products have been recovered from the Indus Valley, although the stamp seals (and the few cylinder seals) typical of Harappan material culture bear a striking resemblance to those invented in Mesopotamia. Objects constructed with typical Harappan practices have been found at Ur, and some scholars suggest that Harappan artisans may have even settled in Mesopotamia. Textual evidence from Mesopotamia records trade with merchants from Meluhha, which may refer to the Indus Valley. Interestingly enough, Mesopotamian texts record that Meluhhan merchants traded in lapis; since this is not found in the Indus Valley, it may indicate that Harappan traders engaged in a more complicated trade enterprise than the mere conveyance of raw materials; they may have been buying and selling for profit.

Trading within the Indus Valley was conducted primarily after the monsoon season. During the monsoons, the rivers would have been too swollen for safe transportation, and the roads would have been too muddy. Given that most sites are located along rivers, the cities and villages were, without a doubt, connected in a larger trade network. The resources that would have been traded within the subcontinent would have been chert and marine shells; archaeologists have been able to reconstruct extensive routes of movements by comparing the findspots of these objects with where they would have originally come from. No doubt these internal trade networks helped facilitate the movement of goods that had been procured from outside of the Indus Valley as well.

Chavin de Huantar— Trade between the Andes and Amazon Basin

The monumental site of Chavin de Huantar is located on the eastern flank of the Cordillera Blanca in the north-central Peruvian Andes. It rests at the junction of two Andean rivers, the Wacheqsa and Mosna (Pukcha), that together merge to the north into the Marañón River, a large tributary of the eastern Amazon River basin. Given its location, the site of Chavin de Huantar may have served as a trade center between the Andes, the western coast, and the eastern tropical forest.

In the 1970s, Donald Lathrap proposed that certain species, floral and faunal, depicted in the sculptural iconography at Chavin de Huantar derived from the Amazonian basin and thus identified the origins of the earliest Chavin populations. Lathrap focused his attention on the Tello Obelisk, an 8.2-foot (2.5-meter) granite shaft recovered from the site's monumental plaza. The shaft is carved in high relief on four sides and depicts an amalgam of images interwoven within and around two nearly identical zoomorphic figures. Following John Rowe, Lathrap identified the two main images as caimans; thus, the sculptural program drew from an eastern tropical forest fauna and mythology. Lathrap likewise branded the other stylized figures, such as felines, birds, and serpents, on tropical forest models and their significance to modern Amazonian populations.

Chavin sculptural images thus appear to comprise the fiercest tropical forest predators: jaguars (*Felis onca*), harpy eagles (*Harpyia harpyja*), caimans (*Melanosuchus niger*), and anacondas. Similarly, the floral species illustrated on

Relief sculpture depicting jaguars and snakes covers the ruins of a stairway at Chavin de Huantar, Peru. (Charles & Josette Lenars/Corbis)

the Tello Obelisk depict Amazonian-based cultigens, such as manioc, peanut, chili pepper, and bottle gourd. Such identifications in Chavin iconography have forced scholars to critically address the nature of trade between the Amazonian tropical forest and the Andean site of Chavin de Huantar during the Late Initial (1100–900 BCE) and Early Horizon (900–200 BCE) periods of Peru.

Trade between the Peruvian coast and tropical forest was occurring possibly as early as the Late Preceramic period (2500–1800 BCE). The site of La Galgada in the Tablachaca Valley, for example, produced colorful feathers of tropical forest birds from Preceramic archaeological contexts. During the Initial period (1800–900 BCE), the site of Kotosh, to the south of Chavin de Huantar in the central Andes, shared in a ceramic tradition with the nearby eastern tropical forest. An imported piranha jaw was even found at the site in a contemporary excavated context. Chavin de Huantar succeeded the Kotosh tradition of the highlands and may have readily maintained connections with the tropical forest, as suggested by its centralized location.

The greatest evidence of long-distance trade during the Formative period, however, exists between the Peruvian coast and Ecuador to the north. The warm-water mollusks, *Spondylus*

princeps and *Strombus galeatus*, from Ecuador were actively imported into Peru from at least the Initial period (1800–900 BCE). These mollusk species feature not only in the archaeological record at Chavin de Huantar but also in the iconographic complex of the Tello Obelisk sculpture alongside the identified tropical forest specimens. The representations of the shells as well as their remains in the archaeological site thus reflect the participation of Chavin de Huantar in a trading sphere that encompassed the Peruvian coast and highlands.

During the Early Horizon (900–200 BCE), sites such as Bagua and Huayurco in the northern *ceja de selva* evince a certain degree of active trade between the Andes and the Amazonian region. Chavin religious practices based on the ingestion of hallucinogenic snuff presumably required tropical forest plants and thus further allude to contact between these two geographic spheres. Nevertheless, very little archaeological evidence remains at Chavin de Huantar to substantiate a clear exchange between the Andes and the Amazon at this site. The tropical species, mythologies, and practices identified by Lathrap and supported by subsequent scholarship at Chavin de Huantar thus require continued archaeological investigation to clarify further the nature of trade or interaction with this presumably highly influential eastern tropical forest zone.

War and Diplomacy

Around 1325 BCE, King Suppiluliuma I of Hatti (the Hittite empire) sent one of his sons to marry a recently widowed queen of Egypt. It is likely that this was the widow of King Tutankhamun, who had died unexpectedly around this time, although the actual name of the deceased king is not preserved. The widowed queen had requested that a royal son be sent to her, an unusual situation since the Egyptians were usually reluctant to allow foreign men to marry into the royal line. These sorts of xenophobic concerns may have been what led someone in Egyptian court circles to have Suppiluliuma's son intercepted and murdered before arriving in Egypt, thus preventing the formation of a dynastic union between two of the most powerful states of the Late Bronze Age: the Egyptians and the Hittites.

The exchange of royal daughters among the great kings of the Near East was only one of the ways that diplomatic ties were created across the Mediterranean and western Asia. Diplomatic messengers moved back and forth freely, bringing with them luxurious gifts to build ties and strengthen alliances. The kings of Egypt, Babylon, Assyria, Mitanni, Hatti, Cyprus, and Arzawa (in Anatolia) treated each other as relative equals (although the kings of Babylon referred to the kings of Assyria with scorn). These kings called each other “brother,” acknowledging that they were the great kings of the world. Kings of smaller polities (most often city-states) called these kings “father,” acknowledging their subservience. This was the milieu of the first treaties. The earliest preserved treaty between equals (known as a parity treaty) was drawn up between the Hittites and the Egyptians. Treaties between nonequals (called suzerainty treaties) were also common.

The Late Bronze Age was a period of relative peace until the so-called Sea Peoples disrupted this international network. In many ways the long period of relative diplomatic stability in the Late Bronze Age was atypical of this period. This was the period when the first states emerged and thus when the first organized warfare between states occurred. The artwork of the

early states in Egypt and Mesopotamia reflects armed conflict. This may be the first propaganda, although scholars debate the suitability of the use of this term for the ancient messages about war communicated in art. From these earliest pieces of art, the king is depicted as skilled in warfare and able to crush his opponents with a violent show of force. Accounts of glorious victories in battle are among the most common historical inscriptions from Egypt and Mesopotamia. Even when the

These kings called each other “brother,” acknowledging that they were the great kings of the world. Kings of smaller polities (most often city-states) called these kings “father,” acknowledging their subservience.

king was not the victor, the king was portrayed as victorious, especially in Egypt. Who would argue these finer points of historical reality with the son of a god?

The tools of warfare became more specialized during this time period. New technologies facilitated the ability to kill. The invention of metal allowed metal weapons to be created, mostly spears, swords, and arrowheads. Armor, made of a combination of leather and bronze, could provide added protection in defense. Chariots allowed archers to move through the battlefield more quickly, avoiding the blows of infantrymen and breaking through the enemy lines. Fortifications—large massive walls—were built to protect the cities. Siege weapons were built to destroy these walls. These technologies developed in China similarly to those that developed in the Near East. In the Americas, warfare continued much as it had in previous centuries, with no new innovations. Metallurgy, as it developed in Europe, seems to have been tied to a warrior culture there. Warriors buried with their elaborate weapons and armor seem to have had a high status within the community, although without textual records their exploits have long been forgotten.

—Kevin M. McGeough

■ Introduction: Technologies of Warfare

Throughout history, many of the great technological advancements have come from military origins. Humans have rarely been as clever at devising new technologies as when they intended these technologies to aid them in war. The concept of an “arms race” is certainly not new; when the first stone tool was used as a weapon, those against whom it was used began to devise better and more effective tools/weapons. The ancient (and still continuing) arms race did not only involve handheld weapons. Ancient fortified cities gave rise to siege equipment, and siege equipment required that fortifications were improved. For each new weapon, large or small, there was a development of better defenses, and for each new defense there were better weapons.

The vast majority of the technological history of tool-using humans has revolved around stone tools, but it was with the advent of metallurgy that the exponential rise in technology began. Bronze first began to be fashioned into tools and weapons sometime in the latter half of

the fourth millennium BCE, and these tools and weapons were generally more durable than their stone counterparts and could also be easily sharpened or recycled if broken. It was, however, many centuries before metal tools and weapons became commonplace. Stone tools were still used for many tasks even into the later Iron Age (ca. 1000–600 BCE), when metals were much more common.

Along with changes in technology came changes in the way in which soldiers were organized. Each new type of weapon required soldiers who were proficient in their use. Siege engines required specialist soldiers just as chariots did. Each new weapon and new type of defense required new manufacturing techniques and the support of other industries. Metal weapons required craftsmen skilled in smelting ores and metalworking, and large-scale fortifications required individuals with knowledge of engineering. Chariots required horse breeders and grooms as well as woodworkers and leatherworkers. As weapons and military technology evolved and

grew, so too did the societies it was used in, and in turn, as societies became more complex, so too did their militaries.

The period from 4000 to 1000 BCE saw the beginning of organized warfare conducted on a level considerably beyond internecine village warfare or even tribal warfare. With the rise of societies such as the Egyptian dynasties and the great city-states in Mesopotamia, the Levant, and India and the Shang dynasty in China, ever-increasing effort was put into the military to both defend these societies and conquer others. As the military bodies grew, hierarchies developed within them, and the culture and society evolved to cope and augment these changes. No study of history can be complete without examining the military and the effects it had on society.

Chariots

The chariot was one of the most important military innovations of the ancient world. It changed the way in which battles were fought and greatly affected the social structure and effectiveness of the military. An ancient chariot was essentially a two-wheeled cart of special design that was drawn by two draft animals, usually horses. Chariots, like any technology, evolved over time from heavy four-wheeled wagons pulled by oxen and other draft animals (ca. early to mid-third millennium BCE) into much more refined forms. By the sixteenth century BCE, chariots were widespread and had gone through considerable changes. They were known from Russia to Egypt, from Greece to India. These later forms were a very valuable item of military equipment. The chariots used in the Late Bronze Age Middle East (ca. 1600–1000 BCE) were lightly built and capable of carrying two or three passengers, which allowed individuals to travel from point to point

➤ SHANG CHARIOT

Chariots are known across the ancient world and were in common use from circa 1500 BCE in Egypt, Greece, parts of Europe, India, the Caucasus, central Asia, and China. In each of these regions, except for China, chariots appear to have evolved from heavy four-wheeled vehicles into light two-wheeled vehicles. This suggests that the chariot did not evolve wholly within China but instead was introduced from elsewhere. One current hypothesis is that chariots were first developed in the Caucasus region of what is now southern Russia and spread in all directions, eventually reaching the regions mentioned above.

Chariot remains have been found in Shang dynasty China (ca. 1600–1050 BCE) in the archaeological excavations at Dasikongcun and Xiaomintun in Anyang Province and Laoniupo in Xi'an Province. Unfortunately, the remains are not complete enough to determine precisely how these vehicles were constructed, so there is still considerable discussion as to exactly how these vehicles would have been used. Some work has been done by researchers at the Royal Ontario Museum in Canada by making a comparison of the Shang dynasty chariots with those found in the tomb of Tutankhamun, the famous Eighteenth Dynasty Egyptian pharaoh (ca. 1334–1325 BCE) in whose tomb six complete chariots were found.

Chariots were a valuable item of military equipment in ancient Egypt, usually being used by elite, wealthy soldiers along with body armor and powerful composite bows. The Shang dynasty chariots have also been found with composite bows and other archery equipment, which suggests that China may also have used the chariot in a similar manner. Much further research needs to be done to determine the origins of the Shang dynasty chariots and the uses to which they were put.

—Thomas D. Hulit

much more quickly than before. The military advantage that this provided was that units of highly trained soldiers could be quickly deployed to where they were most needed, which was particularly useful in battle.

The first known chariots are more accurately called war-wagons. The earliest evidence for the

military use of chariots comes from the Standard of Ur, the decorated sounding box from a musical instrument that was found in the Royal Cemetery at the archaeological site of Ur in 1928–1929. This artifact shows a scene of soldiers, chariots, and draft animals in procession. There are five chariots depicted in the scene, and each is drawn by four hemiones or onagers (draft animals similar to horses). The chariots have four wheels with a chest-high barrier at the front to provide some protection to the driver and passengers. Four of the chariots are shown with a bundle of spears attached to the front, which suggests that the chariots may have been used as mobile platforms from which to fight. Although it is possible that the soldiers fought from the back of the chariot, the four draft animals and the size and weight of the vehicle would have made it slow and cumbersome. It is more likely that these heavy war-wagons were used to transport the elite soldiers to battle as a mark of honor and prestige.

Unfortunately, there is little evidence on the evolution of the chariot between those depicted on the Standard of Ur (ca. 2500 BCE) and those used by the military bodies of the Late Bronze Age (ca. 1600–1100 BCE). However, a great deal of change took place. By about 1700 BCE chariots were of much lighter construction, had only two wheels, and were pulled by two true domesticated horses (*equus caballus*) rather than four. This allowed the chariot to be much faster and more maneuverable.

A chariot or wagon is actually quite a complicated item, and as such it requires considerable technological skills to manufacture. First, the ancient society that desires a wagon or chariot needs to have woodworking skills, the knowledge of how to make wheels, and access to domesticated animals to pull the vehicle. Crude wagons would not be very difficult to manufacture, however. One of the most important technologies needed to manufacture later chariot bodies and wheels is what is called bent wood technology. Essentially, this technology involves using specific types of wood and shaping them in straight sections and then bending them with heat and steam to form the required parts.

The chariots that we are most familiar with are from New Kingdom Egypt (ca. 1570–1070 BCE).

Tutankhamun fighting against the Nubians from his chariot. Panel from the painted wooden chest of Pharaoh Tutankhamun, about 1332–1323 BCE, Eighteenth Dynasty, Egypt. (Roger Wood/Corbis)

Most of the chariots found in Egypt come from the tomb of the famous pharaoh Tutankhamun (r. 1334–1325 BCE). The English archaeologist Howard Carter discovered the tomb in 1923, and in the following years he removed and cataloged all the artifacts within. Included among the thousands of items were six complete but disassembled chariots, each of slightly different design.

In general, the Egyptian chariots were two-person vehicles, some of which were used for military endeavors and some for personal or nonmilitary uses. The cab or body of the chariot is usually about 31 inches (80 centimeters) high (about hip height to allow the passenger to lean against it for added stability), about 39 inches (1 meter) wide, and slightly less than approximately 1 yard (1 meter) long. The wheels are usually about 39 inches or more in diameter, with the axle placed at the rear of the cab. This placement of the axle allows the chariot to be turned quickly but puts more strain on the backs of the horses.

Chariots were often used in the military, but only the elite got to use them. In most instances, the charioteers were members of the social elite, often members of the nobility or royalty. In the Early and Middle Bronze Ages, warriors were infantry along with all the rest of the soldiers. With increasing use of chariots circa 1600 BCE,

elite warriors began to use chariots instead of acting strictly as infantry. Soldiers did not begin to fight from horseback until about 850 BCE, so the chariot was the most advanced weapons and fighting system for almost 1,000 years. The biggest problem was that chariots and horses were very costly to produce and maintain, so there were never as many available to the ancient kings as they would have liked.

Modern literature often makes the mistake of assuming that the chariot was used in a manner similar to modern tanks. This is incorrect for two major reasons: the chariot and horses are not sturdy enough to take the massive impact of colliding with opposing forces, and the chariots and horses were far too valuable to risk in this manner. In the Late Bronze Age, military chariots served several roles. They were often used as vehicles of state, as they were a fine way for the elite to display their wealth, the chariots often being heavily embellished with gold and ornamentation such as those found in Tutankhamun's tomb. They were also sometimes used as fast courier and delivery vehicles, allowing the transport of messages and small quantities of valuable goods.

When the Late Bronze Age chariots were used in battle, they usually served in two ways. They could very quickly transport heavily armed elite soldiers to a point in battle where they were needed, and they also served as mobile platforms for archers. Using the chariots as mobile archery platforms was probably the most common use in the ancient world, as it allowed a small unit of expert archers to travel to the most advantageous place on the edges of the battle to deliver their arrows.

Tools of Warfare—Metal

Though it might not seem so from the era's name, the use of iron did begin before the end of the Bronze Age. However, the use of iron was not widespread, and in fact almost all metal artifacts that have been discovered from the Late Bronze Age were, not surprisingly, bronze. It was not until the twelfth century that the ratio of bronze to iron goods began to shift. Part of the reason for the change was the massive disruptions of trade routes, which occurred by 1100 BCE. Bronze is made by combining copper with tin; both metals, and especially tin, were rare to begin with, explaining the high cost of bronze armor and weapons. The main source of tin seems to have been the British Isles, and when contact with Britain was lost because of invasions, it became nearly impossible to import tin and hence nearly impossible to make bronze. Iron is far more common than copper and tin and is, of

➤ IRON AND THE INFANTRY REVOLUTION

The introduction of iron also coincided with another very important military development. During the Bronze Age, the most important implement of war was the chariot, and the most important soldiers were therefore those who either drove the vehicle or the archers who fired arrows from it. Large infantry units played a role in Bronze Age warfare but generally did so as support troops. It was only late in the period that foot soldiers developed methods to overcome the chariots and therefore inaugurated a new period of warfare in which the infantry was the most prevalent and most important element on the battlefield. Those infantrymen would, of course, now be armed with iron weapons and, in some cases, iron armor.

—Stefan G. Chrissanthos

course, an element, meaning that no additives are necessary. Iron is therefore easier to procure and far cheaper than bronze. In the Dark Age that followed the collapse of the Bronze Age, people needed metals that were near at hand; therefore, iron was increasingly used to make almost everything. Artifacts recovered from the 900s BCE show that for the first time iron was used more than bronze, a dramatic change from just two centuries before. The gap would grow larger even as the Dark Age finally came to an end and new civilizations, with their accompanying long-distance trade networks, developed. Iron eventually would be the metal of choice for almost all armor and weapons made during the rest of antiquity. This meant that almost all the soldiers, from every army, used iron weapons, and if they used armor, that armor was usually made of iron as well. The impact of this cheaper metal on ancient warfare would be incalculable.

Siege Weapons

In the ancient world, siege warfare was an effective, although undesirable, outcome to war. Sieges typically took weeks, if not months or years, and they chiefly involved confining the populace one was attacking within their city and slowly starving them until they either died or surrendered. While this approach allowed for little loss of life to the attackers, it was costly to maintain an army far from home and it was very time-consuming. As such, many forms of heavy weapons and devices were developed to speed the process along. In response to these developments, many new and complex forms of fortifications were also developed.

The first forms of fortified human habitation were simple refuges. These could be as simple as a cave or ravine where a group might seek shelter from an attack. This type of fortification

would probably not have been a good place to stay for extended periods of time, but it would at least limit the direction from which the attacks could come. A better form would be a stronghold, which is similar to a refuge but capable of storing food and other goods. A stronghold is only capable of supporting people as long as its stores of food and water last. Added to this, a stronghold needs to have a group of people to defend it and be situated in a region that is productive enough during times of peace to stockpile a surplus of goods. A very important factor in a stronghold is a secure supply of water. A person can last for some time without food but only a few days without water. Many of the ancient fortified strongholds were built over cisterns or wells (such as ancient Megiddo and Masada).

There is also a form of modified or advanced fortified sites called strategic defenses. These would include outposts (e.g., a series of watch towers) that would serve to warn the main stronghold of imminent attack. Ideally, each outpost or watchtower would be able to signal or send a message to the next tower quickly, thus getting the information to the main fortified center very quickly and giving them ample time to prepare. Strategic defenses may control or overlook quite large distances, such as Hadrian's wall in Britain (approximately 72.7 miles [117 kilometers]) or the Twelfth Dynasty Egyptian forts built on the Nubian frontier between the first and fourth cataracts of the Nile River (31.1 miles [50 kilometers] or more). Strategic defenses can be used to observe the actions and travel of people in a region, but each defensive node or tower in the system is vulnerable. It is a trade between strict defense and the size of the area it controls.

Over time the fortifications were adapted and changed in response to the military methods of the age. As fortifications became more sophisticated, so did the weapons used against them. In order to end a siege more quickly, new techniques and great war machines were developed. The first of these new innovations was the battering ram. The earliest solid evidence for a battering ram comes from a relief in the tomb of Khety, an Egyptian provincial governor of the late Eleventh Dynasty (ca. 2000 BCE). The depictions show infantry soldiers attacking a fortress

while three soldiers use a long pole from within a light shelter to dig at the walls with the intention of making them collapse. It was some centuries later that the true battering ram is first known to have been used to knock down the gates of a city (e.g., the early Iron Age). Initially, it was simply a large log, often with a metal cap, carried by a group of soldiers and used to batter down the gates. Later in history, and certainly by the Assyrian period (ca. 900–600 BCE), this ram was suspended within a movable covered framework to provide protection for the crew and make swinging the ram much easier. An example of this is shown on a relief in the British Museum of the destruction of Balawat's gates and the surrender of King Hamath (Assyrian, ca. 900 BCE).

Large siege engines and siege towers were not common in ancient Egypt due to the lack of wood; however, they did occur in primitive forms. In a relief in the Fifth Dynasty tomb of Inti at Deshasheh (ca. 2450 BCE), there is evidence of tall ladders being used by Egyptian forces to scale the walls and capture a fortress in what is now Israel/Palestine. Later, in the Eleventh Dynasty, there is a relief from the tomb of the general Intef at Thebes showing large ladders or crude siege towers also being used to capture a city. In later centuries, larger wooden siege engines, such as mobile towers covered in wet animal hides (to keep the enemy from burning them), were developed and used in places such as Assyria (ca. 900–600 BCE). Generally, large siege engines were manufactured on site due to the difficulty in moving them over even relatively small distances.

Prior to 1000 BCE siege weapons were in their infancy. The fortifications of the time were designed and evolved primarily to prevent attack by regular infantry soldiers. Steep slopes on the outside faces of the walls called the *glacis* were designed to make it very difficult or impossible for a soldier to climb. These sloping faces would also make it impossible for early siege towers to get close enough to do any damage. Heavy missile-throwing engines such as catapults and trebuchets were only invented many centuries later. True catapults and torsion engines were not developed until later in the first millennium BCE.

Egyptian Execration Texts

The Execration Texts provided a kind of curse that the ancient Egyptians directed against threats that were beyond immediate reach. Such threats included real-world foes as well as perceived supernatural forces and other intangible dangers. Two primary steps comprised the basic execration ritual: identification and destruction. The victim's name was usually applied on an

object—a red pot, a figurine (of clay, wood, or wax), or a plaque—in order to give it an identity. This could be accomplished by writing names alone or by using a full execration inscription. However, blank execration figures suggest that verbal naming would suffice, and a complete execration ritual probably included recitations. The final steps in the process were the breaking or burning of the object followed by burial.

This was not so much household magic as a ritual practice used on behalf of the state to help maintain order in the world. Execration rites

were supposed to negate the harmful magic or supernatural influences that could be directed against Egypt by enemies from this world or beyond. The most common targets were foreign peoples, specifically Egypt's traditional enemies: Nubians, Asiatics (from Syria-Palestine and the broader Near East), and Libyans. Many Execration Texts appear on crudely shaped figurines in the shape of captives, often shown bound with arms pulled behind their backs. In Egyptian iconography this posture was a very common mode of depicting foreign enemies. Such human-shaped figurines were not like voodoo dolls, though, as the person or people they depicted were not necessarily expected to experience immediate, direct effects. Also named in some texts are malevolent spirits of the dead, including Egyptians. Conceptual dangers included potential evil acts and even bad intentions harbored against Egypt.

Execration Texts are known from the Old Kingdom until well past the New Kingdom. By the Middle Kingdom a fairly consistent format had developed. Early sections list specifically the leaders of enemy foreign groups, their home regions, and their affiliates. A so-called Rebellion Formula mentions generically anyone who would rise up and fight against Egypt. Groupings of dangerous actions, sentiments, and spirits receive their own sections as well. At the Nubian site of Mirgissa a sizable deposit of broken execration objects dating to the Middle Kingdom may suggest that this kind of ritual was part of the foundation ceremony for the Egyptian fortress there. The remnants of an associated human sacrifice may also indicate that execration rites were not always restricted to just symbolic ritual objects.

Mercenaries

Throughout history it has always been difficult for governments to find enough good soldiers. A soldier's life was and is often very hard, and there is the ever-present danger of loss of life, so for many a military life was not desirable. Warfare in the period from 4000 to 1000 BCE generally involved either local disputes or in some cases wars waged far from home. For example, Thutmose III (ca. 1504–1450 BCE) waged 17 military campaigns outside of Egypt during his reign. Military life for the Egyptian soldiers at this time included long periods away from home and away from their families and professions. Life in the military was often not popular, and many societies in the ancient world suffered shortages in personnel.

Conscription was one obvious way to deal with the shortage, and many ancient cultures adopted it. In the Old and Middle Kingdoms (ca. 2600–1780 BCE) Egypt conscripted 1 in every 100 men into the army, and by the time of Ramesses II (ca. 1279–1212 BCE) 1 in 10 men were being conscripted. This was very unpopular, and many Egyptians avoided conscription by hiding or running away. The only way for Egypt and other societies to gain enough soldiers to maintain a large enough standing army was by hiring mercenaries. The period from 4000 to 1000 BCE was premonetary, so mercenaries were not paid in coinage but instead were often given grants of land and a share in the loot from the battle. A military career in Egypt, whether as a mercenary or a regular soldier, was one of the only ways for a peasant or commoner to increase his status and fortune in life.

The first solid references to mercenaries are from the reign of King Sargon of Akkad in Mesopotamia and date to ca. 2350 BCE. Sargon employed perhaps as many as 5,000 mercenaries, mostly recruited from the edges of his empire. These mercenaries also sometimes saw regular police duty and were often used to put down internal riots and revolts. Since they were far from home, they would have no connection with the people they had to control, and Sargon did not have to make his soldiers use violence toward their own people. This allowed Sargon to see his will done without much unrest developing

within his military. The Egyptian pharaohs often used the famous Medjay Nubian mercenaries in a similar way. By the time of the Egyptian New Kingdom, the Medjay were unofficially known as the Egyptian police force.

The most notable force of mercenaries in the ancient world were the Habiru. This group or culture was known across the ancient Middle East and appears in the documents of many cultures from 2500 BCE through to about 1000 BCE. Its origin is unknown, and there were groups of Habiru in many regions. The ancient texts note that they were sometimes hired for domestic purposes but most often as mercenaries. By the fourteenth century BCE the Habiru had become very successful as mercenaries, and their population had grown to the extent that they were able to take control of various towns and cities in the Levant, including Hazor and Byblos. However, with the collapse of the great city-states at the end of the Late Bronze Age (ca. 1050 BCE), the Habiru disappear from history. It is possible that in all the upheaval of the period they were incorporated into what remained of society after the fall of the elite polities of the period.

Bronze Age Fortifications in Syria-Palestine

Fortifications are large walls and gate systems that are built around cities to act as defensive barriers against military invaders and to regulate the movement of people in and out of a city. Perhaps due to their location between the great powers of Asia (Mesopotamia, the Hittites) and Africa (Egypt) and the city-state political system of the region during the Bronze Age, the cities of Syria-Palestine developed some of the most sophisticated fortification systems in the ancient world. As protection from the larger armies of the states to the south and east of the region and probably more importantly as protection from nearby rival cities, the cities of the Levant built large walls to defend their cities.

The first substantial fortifications appear in the Early Bronze II (EBII) period (3050–2700 BCE), in tandem with a process of intensive urbanization. As large cities began to develop, so did defensive architecture. These first fortifications are simple stone walls, perhaps 9–13 feet (3–4 meters) in width at most. Construction techniques vary. Some sites have towers connected,

most likely to defend weak sections of the wall (especially the gates). EBII towers are rectangular or horseshoe shaped.

The EBII fortifications are enlarged and strengthened in the Early Bronze III period (2700–2300 BCE). For example, the EBII tower at Tell el-Farah (north) was expanded from 9 feet (3 meters) in width to 23 feet (7 meters) in width. Some of these walls were expanded using larger stones; others had retaining walls added. At Yarmuth, which had the largest EB fortification system (surrounding 40 acres of area and preserved archaeologically to a height of 26 feet [8 meters]), the old wall was supplemented by a new outer wall. This outer wall was attached directly to the exterior of the older wall, and the exterior of the new wall was plastered.

Fortification systems fell out of use in the Early Bronze Age IV/Middle Bronze Age I period (2300–2100 BCE), which was a time when cities were abandoned in favor of small village settlement and seminomadic subsistence patterns. When people started building cities again, in the Middle Bronze Age II (MBII) period (2100–1550 BCE), the art of fortification reached a previously unparalleled level of sophistication and size. These fortification systems were so massive that the topographies of entire sites were transformed. The general principle behind MBII fortifications was to raise the level of the city wall high above the surrounding plain. The farther away from the slope of the hill that the city wall could be located, the less useful siege weapons (like battering rams) were for the attackers. Two general types of fortifications were used: the earthen rampart and the glacis.

The earthen rampart was constructed by dumping earth and soil in huge piles on either side of a tall vertical core, creating an artificial mound that wrapped its way around an entire city. These vertical cores could be quite large; at Tell Dan and at Hazor, these cores are 32 feet (10 meters) high and 32 feet (10 meters) wide. As Amihai Mazar describes them, these earthen ramparts created large craters inside of which cities developed. They were usually built in geometric shapes and are very distinctive from natural topography.

Earthen ramparts were most useful for sites that were located on low-lying surfaces. If a slope

➤ KEEPING PEOPLE IN A CITY— WHAT WENT ON AT A CITY GATE?

City gates were lively places in the ancient Near East. People would come to the gate to exchange goods, have goods weighed, and have documents written for them (such as contracts or letters). Beyond these services, in some cities town councils or elders met at the gates to discuss matters of law or civic governance. Guards were likely posted at city gates. The so-called Laws of Eshnunna, which date from around the end of the nineteenth century and the beginning of the eighteenth century BCE, discusses legal actions regarding slaves near gates. Slaves who enter the city are bound to wear marks of slavery, fetters or distinct hair cuts. Anyone bearing these markers of slavery is forbidden from exiting the city. Similar laws in the book of Exodus from the Old Testament suggest that the policing of slaves at city gates was widespread throughout the Near East.

—Kevin M. McGeough

already existed, a glacis was constructed instead. A glacis is based on similar principles to a rampart, but since a large slope already exists, there is no need to use an inner core or build an inner slope. Instead, the angle of elevation of a slope is simply enlarged (usually to around 30 degrees in slope) to undermine the effective use of siege weapons. Glacis are built up of large amounts of earth, stone, or anything else that could be used as fill. The first glacis are found in the EBII/III period, but the size of these artificial slopes is substantially larger in the MBII.

City gates in MBII were protected by flanking towers, as in the EB II/III period. Gate entrances were typically built to provide a bent-axis entrance to the city, which weakens the position of the attackers. Attackers, when running into a city, were forced to turn immediately to their right, exposing their weak side to defenders (presuming that most soldiers fought right-handed) and limiting the speed of wheeled vehicles.

Fortified Third-Millennium Settlements in China

During the third millennium BCE, a large number of settlements enclosed by walls appeared all across China. Excavations and surveys in past decades have revealed at least 50 such settlements dating to this period. A presumed urbanization of this kind is commonly regarded as marking a development of prehistoric (primitive) society from other forms of sociopolitical organizations, such as chiefdoms, into a state-level society. For China, the prevailing scholarly opinion views the appearance of regional or city-states, thereby marking the beginning of Chinese civilization.

However, enclosed settlements are not an invention of the third millennium BCE. The earliest known walled settlement appeared at Bashidang

in northern Hunan Province, which was dated to the late sixth millennium BCE. Other contemporary settlements were enclosed by a moat. Rather well-known are the fifth-millennium BCE moated sites in north-central China, such as the one at Banpo, Henan Province, the only Neolithic settlement that has been entirely excavated to date. Larger walled settlements, often also surrounded by moats, appear during the fourth millennium both in North and South China. Most of the walls were built using the pounded-earth technique. At the Xishan site in Zhengzhou, Henan Province, the technique to use wooden support frames within which the earth was pounded was first observed. This technique should have been in use during the ensuing thousands of years.

During the third millennium there was a sudden increase in walled sites. Although some earlier ones remain in use and were enhanced, most walls were constructed during this time, sometimes also around previously open settlements. These sites are distributed over vast areas in China with concentrations along the Yellow River in Shaanxi, Shanxi, Henan, and Shandong provinces and the Autonomous Region of Inner Mongolia as well as along the upper and middle reaches of the Yangzi in the provinces of Sichuan, Hubei, and Hunan. Most of these settlements remained occupied throughout the third millennium, and only some of those in Sichuan may have been occupied during parts of the second millennium as well.

Most of the 22 walled settlements along the middle and lower Yellow River were found on elevated areas in the plains or alongside rivers. The majority are square or rectangular in shape and encompass an area from 322,920 to 21.528 million square feet (30,000 to 2 million square meters). The walls were often built on underground foundations made of pounded earth and were surrounded by moats. Almost 20 walled sites were identified in Inner Mongolia. Unlike their counterparts in other regions, their walls were built with stone. They were typically constructed at the feet of mountains or on high banks of the Yellow River; the sizes range from around 107,740 to 2,961 million square feet (10,000 to 250,000 square meters). At least 10 walled settlements can be found along the middle Yangzi. Their irregular shape often follows

➤ TAOSI—A WALLED SETTLEMENT IN XIANGFEN COUNTY, SHANXI PROVINCE, 2500–1900 BCE

One of the most important walled settlements in north-central China is Taosi. Since 2000, large-scale excavations have revealed the eastern, northern, and southern pounded-earth walls, which form a rectangle with rounded corners of approximately 29.06 million square feet (2.7 million square meters) in area. Built during the middle phase of the site (2400–2100 BCE), this larger wall encloses a walled settlement of 6.03 million square feet (560,000 square meters) located in the north-eastern corner, dating to the site's first phase (2500 BCE). Next to the south wall of the larger enclosure another walled settlement of the middle phase (107,639 square feet, or 10,000 square meters) was discovered. It is not clear whether it is a component of the large site.

Although large rammed-earth building foundations, probably of residences, were discovered, the excavations have concentrated on the cemeteries. A huge cemetery dating to the whole period of the site and yielding many thousands of tombs is located at the southeastern corner. Since 1978, approximately 1,300 tombs have been unearthed. Over 90 percent of the tombs contain no or only a couple of grave goods, while only 1 percent were lavishly furnished. These tombs contained painted wooden coffins and various objects, such as painted pottery, wooden and stone artifacts, and musical instruments (e.g., drums and stone chimes). The considerable amount of energy invested into these rich burials may indicate the existence of a social hierarchy at this site. Another mid- to late-period cemetery was found at the northwest of the smaller walled site to the south with mostly large tombs containing jades, lacquerware, and painted pottery.

—Sascha Priewe

natural elevations and river courses. The latter are also often incorporated into the moats that surround the pounded-earth walls. The sizes range from 645,850 to 12,916 million square feet (60,000 to 1.2 million square meters). Around six walled settlements were identified in the Chengdu Plain of Sichuan Province. Ranging in size from 1.064 million to 6.458 million square feet (100,000 to 600,000 square meters), they

were all built on elevated spots. Most are rectangular in shape, and some have up to two walls of pounded earth with moats possibly running between and along the outside of the walls. One large walled settlement of 31.215 million square feet (2.9 million square meters) in size was found in the area of the Yangzi Delta.

Why do we witness an increase in walled sites during the third millennium BCE? The most common explanation regards the fortifications as an outcome of a growing need for protection due to an increase in violent conflicts. Warfare may have been one reason to promote the construction of defensive features around settlements. However, it remains to be studied how defensible these settlements actually were. Thus, other reasons may also play an important part, such as flood prevention, particularly in the monsoon-prone south-central regions. Furthermore, it is thought that these sites were locations of high ceremonial and ritual value. After all, they had often been inhabited for a long time prior to wall construction.

Despite other potential explanations, which have not been fully explored yet, walled settlements are largely seen as political centers of either regional states or city-states. A high degree of sociopolitical organization may be supported by the settlements being surrounded by a large number of smaller open villages that may have depended on and been integrated into such a state. The archaeological search for rulers is considered successful for some sites, such as Taosi in Shanxi Province, where large and elaborate tombs may mark the final resting places of the local elites. Furthermore, the manufacture of richly carved jade objects is believed to imply not only specialized craft production but also ritual activities centering on the elites from whose tombs they were primarily excavated.

Problematically, most of this evidence has been assembled from various sites across China, thereby neglecting regional differences. This paints a misleading picture of a uniform Late Neolithic China in terms of sociopolitical organization. However, this uniform picture is believed to support textual accounts about the *wan guo* (10,000 states), a notion that came to be favored for explaining the existence of walled sites. Needless to say, basing archaeological interpretations

on legendary texts, which were compiled many thousand of years after the archaeological evidence was formed, is devoid of any foundation. Nevertheless, these notions remain very popular despite lacking scholarly rigor.

On the other hand, the notion that third-millennium BCE walled settlements may reflect the existence of states and thus the rise of civilization in prehistoric China, regardless of later texts, would be supported if they indeed represented cities (an urban revolution). But to date we lack generic criteria in order to define the Chinese city. This situation is compounded by archaeological fieldwork that is primarily directed to investigate the walls, cemeteries, and often only limited remains of residential areas. We lack archaeological research directed at identifying the functions and uses of walled sites as well as

their populations. Research also needs to go beyond reliance on ancient texts. This is also true for simply applying the evidence for actual later Bronze Age cities (ca. 1600 BCE and later) to the Neolithic case.

■ Introduction: Experiences of War around the World

Warriors and warfare were glorified in Greece and much of the rest of western Europe during the Bronze Age. The stories of Homer, which were written down after 1000 BCE but likely reflect earlier values, glorify the actions of the ancient warriors involved in the Trojan War. Heroes like Achilles were glorified because of their skills at warfare, and the Homeric epics describe their battles and their accoutrements of warfare in great detail. In other parts of Europe in the Bronze Age, men were buried in elaborate armor and with weapons, suggesting a glorification of warfare beyond the grave.

Warfare was not just glorified in ancient Europe. Hints of the celebration of wars and warriors abound in Mesopotamian culture. Artistic images, such as the so-called Standard of Ur, depict soldiers and war-wagons triumphing over enemies and leading away prisoners. In the mythological text known to scholars as *Erra and Ishum* a group of divinities (personified weapons) describe war in glowing terms, saying that "to go on to the battlefield is as good as a festival for young men." Mesopotamian kings such as Shulgi bragged about their prowess at war and

imply that these skills at warfare are part of what makes them good kings. Egyptian kings similarly boasted about their prowess at war and commemorated their victories in wall reliefs and historical accounts.

The real horrors of warfare were also acknowledged in the ancient world. Antiwar sentiments are present in poetry of Zhou China. Pacifistic tendencies in the ancient Near East seem to have been based more on pragmatic grounds than on moral grounds. For example, arguments against warfare in wisdom literature suggest that it can be a waste of resources and implore careful planning when entering a combat situation. For the most part, war was understood to be an expected (if not always acceptable) component of ancient life. The following entries explore the varieties of experiences of warfare in the period 4000–1000 BCE throughout the world.

—Kevin M. McGeough

Early Israelite Warfare

The Hebrew word for war occurs 319 times in the Hebrew Bible (Christian Old Testament). There

are fewer attestations of the Hebrew words for instruction, covenant, sin, and family than for war. Warfare played a significant role in the formation of religion in addition to the forging of the Israelite state. One reason for this constant warfare was Israel's geographical location, since it was situated between Egypt in the south and Mesopotamia in the north. The superpowers that arose in these regions contended for the land surrounding ancient Israel, which served as a military buffer zone (and vantage point) and provided a monopoly over trade to those in control. According to biblical tradition, in the Period of the Judges, before the reign of King David, Israel had only a militia. It was assigned into units: 1,000, 100, 50, and 10. Adult males, 20 years and older, were expected to participate when called upon (Num. 1:3). They were levied according to family and clan (Num. 1:2), over which certain individuals were named as leaders. There are frequent examples of taking censuses for the levying of soldiers (e.g., Num. 1; 2 Sam. 24:1–9). A soldier may even have had to furnish his own weapons and food (1 Sam. 17:17). Mercenaries may have been brought in for their special military skills, though they are not visible until the time of the monarchy.

In those early days of warfare Israel had neither a standing army nor chariotry. Warfare fell into two wide-ranging divisions: siege warfare and open warfare. In the latter, Israel depended mostly on its infantry, which consisted of three main units: the spearmen, who engaged in hand-to-hand combat; the archers, who assisted the spearmen from the rear; and the slingers, who worked in pairs behind the archers. Strategically, Israel implemented various types of military tactics from psychological warfare to surprise attacks. They made use of guerrilla warfare and manipulated the immediate environs to their advantage. In the case of David and Goliath (1 Sam. 17), we observe the ancient custom of holding a duel to decide who would take home the victor's crown.

In terms of religion and social ideology, as it is presented in the Hebrew Bible (and the ancient Near East), warfare—or so-called Holy War—functioned as much within the realm of the divine as within the national realm. It was not the king who called the troops to battle but rather

Yahweh, the national deity of Israel. Moreover, the battle was not fought by human strength; instead, it was Yahweh who claimed victory over enemies, who in turn were identified as “Yahweh's enemies.” When Yahweh waged war, a kind of “confusing divine terror” overcame his foes, thus putting them to rout. Thus, in warfare as in other social institutions of the ancient world, there was no distinction between religion and affairs of state. In addition, though there is some doubt about certain biblical accounts, in the main the traditions behind the institution of Holy War are ancient and authentic.

Mycenaean Warfare and the End of the Minoans

The Mycenaeans emerged on the southern Greek mainland in the seventeenth century BCE, when Minoan civilization was at its height. It is clear from their burials that theirs was a society in which the warrior played an important part. The most magnificent burials are those found in the Shaft Graves at Mycenae, some with gold death masks. Examination of their bones shows that many had suffered injuries and skeletal stress from years of fighting. Their grave goods included plates from boar's-tusk helmets, gold decorative breastplates, and many weapons. Among these was a dagger inlaid with a hunting scene in which warriors are shown armed with swords, bows, and spears, and carrying figure-of-eight shields or tall rectangular (tower) shields with curved sides. The dappled appearance of shields depicted in frescoes shows that they were made from oxhides, presumably over a wooden frame. These shields were particularly suitable for single combat, where they offered a full protective screen between the combatant and his opponent,

but they were less useful in a pitched battle, where attack could come from any side. Depictions on stelae marking the graves show soldiers equipped in the same style. Spearheads from the Shaft Graves and other early contexts included a type with a split shaft mounted into a shoe on either side of the blade; this soon went out of use. A more efficient type, with a socket at its base to take the shaft, was current throughout the Mycenaean period. These spears were used for thrusting; there is no certain evidence of the throwing spear frequently mentioned in Homer's *Iliad*.

Later Mycenaean frescoes and depictions on pottery show that many of these armaments continued in use, and new ones were added including greaves (shin guards) and corselets (cuirasses). A smaller round shield more suitable for maneuvering in pitched battle replaced the earlier types. A set of armor discovered near Midea (the Dendra Panoply) included a helmet, bronze greaves, and a corselet made of overlapping bronze half-rings and plates covering torso, shoulders, neck, and the tops of the arms, combining protection with flexibility. These seem to have been stitched to a linen garment, probably well padded, while the helmet originally consisted of a leather cap to which were added slices of boar's tusk arranged in rows that curved right and left alternately and ear guards made of bronze. Helmets usually had a chin strap and might also have a neck guard. Boar's-tusk helmets would have been restricted to the elite, since each required the tusks from 20 to 40 boars; ordinary soldiers wore helmets and body armor of leather or thick layers of linen to which bronze disks might be sewn as reinforcement.

Swords used by the Mycenaeans changed through time. In the Shaft Grave era, a narrow rapier was used: this was hafted with a very short tang that would easily have broken, and examples with longer tangs were also developed. The rapier was designed for thrusting into the body of an enemy or hunted animal. During the fourteenth century this was replaced by the two-edged slashing sword with an integral hilt to which a handle was fastened with nails. Arrows in this period were tipped with bronze heads, often with tangs; earlier arrowheads had been made of flint or obsidian.

The Warrior Vase, from Mycenae, about 1300–1100 BCE.
(Nimatallah/Art Resource, NY)

Stelae from the shaft graves, terra-cotta models, and pottery decoration show that the elite drove chariots with four-spoked wheels drawn by a pair of horses; chariots, dismantled chariots, and chariot wheels are among the items in storage listed on the Linear B tablets from Knossos and Pylos. These allowed the aristocracy to move with speed as military messengers and to travel in style to the battlefield and, when necessary, in retreat from it; it is unlikely that they were used as mobile fighting platforms.

On a larger scale, ships were used as transports, but the depictions of two ships on a vase from Iolkos show that they were fitted with a ram and thus were also used offensively. A few late Mycenaean sherds may depict sea battles. The Pylos tablets refer to musters of troops as rowers for naval defense. Ships seem generally to have been propelled by oars but also had sails for use when winds were favorable.

By 1450 BCE the Minoans, who had strongly influenced the Mycenaeans in earlier centuries, were in decline. Of the palaces and towns, all but Knossos were destroyed at this time. The cause is still uncertain: it may have been internal strife or natural disasters, such as the earthquakes that frequently troubled the region, or the Mycenaeans may have been implicated. If they were not, they certainly stepped into the power vacuum left by the Minoan collapse, establishing themselves at Knossos sometime around or after 1450 and gradually taking over the eastern Mediter-

► THE TROJAN WAR AND MYCENAEAN WARFARE

The great Greek epic the *Iliad* recounts episodes from a ten-year war between Greeks of the heroic age and the inhabitants of Troy in coastal Anatolia. It is traditionally attributed to the Greek poet Homer, who lived during the eighth century BCE, and probably builds on earlier versions of the story. Long thought to be purely myth, the story was shown to reflect a real period of Greek prehistory when, in the late nineteenth century CE, Heinrich Schliemann excavated at Mycenae and revealed the existence of the Mycenaean civilization.

Some details of Homer's epic poem are anachronistic, but many genuinely reflect Mycenaean society. One of the most famous elements in the *Iliad*, the Catalogue of Ships, has been lent support by information in Linear B tablets recently discovered at Thebes. Many of the places listed as contributors to the war fleet are named in these tablets, some of them settlements no longer occupied in Homer's day. There is a much less good fit, however, between the place names of the catalog and those of the Pylos tablets. And there is no evidence that the Trojan War itself actually took place.

The fall of Troy is dated in Greek tradition to 1184 BCE. Since the late 1990s, excavations at

Troy and elsewhere have been revealing a historic picture into which the Trojan War could well fit. The large city of Troy VI, which may have housed 6,000–10,000 people within a walled citadel and a walled outer town, was destroyed by an earthquake around 1300 BCE. When the Trojans rebuilt their homes (Troy VIIa), they crowded inside the citadel wall as if for protection against an external threat such as a besieging enemy. A few letters exchanged between the ruler of Troy and his overlord, the Hittite king, refer to attacks on Trojan lands during the thirteenth century BCE, in some cases explicitly by Ahhiyawa (probably identifiable as the Mycenaeans). The city of Troy VIIa was destroyed around 1200 (between 1230 and 1180) BCE. Piles of slingshots in the street ready for use by the defenders and bodies, spearheads, and arrowheads in the ruins show that it fell to enemy attack. There are other possible explanations for the sack of Troy. For example, this was the period when the Sea Peoples were actively raiding, but the evidence now available shows it possible that the *Iliad* has its roots in genuine Mycenaean history.

—Jane R. McIntosh

raean trade network that the Minoans had so successfully operated. Warrior graves on Crete, at Knossos, and elsewhere, were probably the burials of Mycenaeans, complete with swords, spears, and helmets. Minoan life on Crete nevertheless continued, though with a strong Mycenaean veneer. Around 1375–1350 BCE Knossos was destroyed, perhaps by the Mycenaeans, and the center of power on the island shifted to Khania in the west.

During the fourteenth century BCE, palaces emerged on the mainland, often on citadels with impressive walls that in some cases were constructed of massive stone blocks (cyclopean masonry). These may initially have been intended as much to impress as to defend, but in the thirteenth century many walls were extended to enclose far larger areas, and defensive measures were added. At Mycenae, for example, the extensions included a bastion with a sally port and a subterranean passage to an underground cis-

tern, giving the inhabitants access to water if besieged. Similar arrangements for access to water were made at Tiryns and Athens, and at Tiryns the extended walls contained corbelled passages and storage chambers, again suggesting provision against a siege. Frescoes and decorated vessels portray sieges, with warriors fighting outside the walls—watched by women at the window—and slain defenders tumbling from the walls. Many of the palaces were destroyed by fire around 1200 BCE, perhaps as a result of social unrest or internecine conflict.

At Pylos in coastal southwest Peloponnese, however, the enemy came from the sea and may well have been raiders belonging to the Sea Peoples who were wreaking destruction in the eastern Mediterranean around this time. One of their victims may have been Crete: the remaining centers were destroyed, and the inhabitants fled to the hills where they established impoverished refuge settlements. At Pylos was found an

archive of Linear B tablets covering the palace's final year; a set of five tablets (headed "Thus the watchers are guarding the coastal regions") deals with the provisions for coastal defense. Eight hundred men were deployed in groups along the coast; their purpose, it seems, was to give the palace early warning of any imminent attack from the sea, presumably so that a large force could be deployed to where danger threatened. Despite these precautions, the palace was sacked and burned, and the kingdom was largely abandoned. Some Mycenaeans who survived the troubles of this period fled to start a new life in Cyprus or farther afield; others, in small numbers, reoccupied many of the towns and citadels, although they did not refortify them. But the glories of Mycenaean society were over.

Early Warfare in Mesopotamia

In the Early Dynastic (ED) period (2900–2350 BCE) armed conflict arose generally from competition between settled states for land and water or by nomad raiders. Expeditions abroad to obtain commodities not available locally might also need armed protection or aggressive "sales tactics"—hence, for example, the fortifications around the Uruk-period settlement at Habuba Kabira and the military threats uttered by Enmerkar of Uruk against the distant state of Aratta. Unequivocal evidence of armed conflict in Mesopotamia comes in the late fourth millennium BCE, with artwork on seals depicting fights between men armed with spears and bows, and bound prisoners. During the earlier third millen-

nium (ED period) cities, often housing the bulk of their state's population, began erecting walls for defense as well as for territorial demarcation and prestige. Excavation has confirmed the slightly later literary descriptions of Uruk's city walls: a circuit 5.9 miles (9.5 kilometers) long and 13–16 feet (4–5 meters) thick built of typical ED plano-convex bricks enclosed an area of 2.12 square miles (550 hectares). At least two city gates with rectangular towers have been traced, and the wall may have had as many as 900 semi-circular towers. Similar towers have been found in the strong walls around Tell Agrab on the Diyala.

The epic tale of conflict between Gilgamesh, king of Uruk, and his one-time benefactor and overlord, Agga, king of Kish, climaxes when Agga's forces besiege Uruk and Gilgamesh defeats and captures Agga, possibly after a pitched battle. Sieges in the ED period were often decided by force of arms in attacks and sallies rather than by attrition during long investments. However, attempts might be made to break into a fortified settlement using scaling ladders, and defenses began to be enhanced with a glacis.

The walls of captured cities were broken down, partly to humiliate their citizens. Booty and prisoners were taken, and much of the city might be sacked. Some of the spoils of war went by custom to the king and some to the god of the victorious city in his temple. Stone bowls found in the Ekur temple in Nippur bear inscriptions showing they were booty from King Rimush's Elamite wars. Such inscriptions were an important part of the offering, demonstrating to both the god and the people that the king had fulfilled the god's intention in prosecuting war and benefiting his people. Inscriptions quickly grew in length and substance from their terse early-third-millennium beginnings, and by the first millennium, royal inscriptions gave a long and detailed, although often exaggerated and inaccurate, account of the campaign, serving both as justification to the god and propaganda to the people. The form, style, phraseology, and content of inscriptions were dictated by tradition.

In conflicts between Sumerian city-states the victor usually respected the integrity of a defeated city's temples: outrage at King Lugalzagesi's failure to do so is forcefully expressed

in the inscriptions of his enemy, Uru-inim-gina of Lagash. In contrast, attacks by outsiders—nomads of the Syrian Desert and Zagros Mountains, such as the Amorites and Gutu, and foreign states, particularly Elam—were ruthless and spared nothing and no one. Sumerian distress at the devastation wreaked by their attacks—the noble buildings destroyed or infested by the enemy, the fields laid waste, the people slain or taken into captivity—is poured out in a series of lamentations describing the sack of great cities like Akkad, Ur, and Nippur.

ED art vividly captures the citizen armies of the period. “The Standard of Ur” and “The Stele of Vultures” depict foot soldiers armed with spears or pole-mounted axes, their heads protected by leather or felt helmets. A force of heavy infantry carrying large rectangular shields marches in a solid and impenetrable phalanx bristling with couched spears, behind a king armed with a dagger. Maces and throwing sticks were also used as weapons at this time. The leaders ride in ponderous war-carts with four solid wheels, drawn by donkeys or mules. These were used mainly for transport to the battlefield and in pursuit of retreating enemy forces, and as a vantage point from which the leader could see and be seen, to direct his forces and impress friend and foe. The dead of the opposing army lie beneath the wheels of the carts or are heaped up in a communal burial mound, while the living are marched off into slavery, their hands tied behind them, or are held in a net by the god whose approval of the victors’ just cause had precipitated the conflict and ensured its successful outcome. Later wars by larger states enjoyed the support of the war goddess Ishtar (Inanna), Nergal (Erra), god of strife, and the storm god Adad (Ishkur). Defeat, and even more terribly, the loss of the king in battle, betokened the withdrawal of divine favor.

Troops also included archers and soldiers armed with slings and ovoid stones, probably mainly recruited among the hunters and fishermen of the south. An inscribed object from the ED period at the site of Mari shows a Bowman shooting from behind a wicker screen held by a spearman: this combination of archer and shield-bearer continued down the ages in Meso-

potamian armies. The later-third-millennium development of the composite bow revolutionized warfare. Constructed as a sandwich of three contrasting materials, wood glued between a horn inner layer (to resist compression) and a sinew outer layer (for elasticity), it had a far greater penetration and range (around 575 feet or 175 meters) than the conventional bow. The composite bow benefited both attackers and defenders, enabling a wider area to be covered from the walls and troops on the ground to shoot defenders with more success.

Order versus Chaos— Egyptian and Near Eastern Justifications for War

The forces of order and chaos waged a constant battle in ancient Egypt and Mesopotamia. The civilized world, as it had been created and organized by the gods, was under constant threat of attack both by untamed forces within its borders, such as wild animals, and by uncivilized human enemies from other territories. In both Egypt and Mesopotamia, wild animal hunts and wars were characterized as cosmic battles between order, as represented by the king and his army, and chaos, as represented by the enemy and its alien customs and appearance.

The Mesopotamian city-state was both the center and the symbol of the divinely ordered

world. The king, as the representative of his city's patron god, was bound to defend the urban and agricultural lifestyle against the constant encroachments of chaos, as represented by the various nomadic groups inhabiting the steppes and mountains on the borders of Mesopotamia as well as by the hostile polities that arose in more distant regions such as Iran. Both nomadic tribes and organized political adversaries were characterized as dangerous sources of disorder in contemporary texts, and their barbaric and uncouth practices were negatively compared to the civilized customs of Mesopotamia. In some cases, human enemies were even bestialized, emphasizing the extent to which they differed from the Mesopotamians and making them legitimate targets of military aggression. In the Marriage of Martu myth the nomadic Amorites, a constant threat to Mesopotamian city-states since the time of the Ur III king Shulgi (ca. 2094–2047), are compared to monkeys in appearance and are described as completely uncivilized in behavior. A royal inscription from the reign of Shu-Sin (ca. 2037–2027), whose reign was plagued by Amorite incursions, similarly dehumanizes them: they are compared to dogs or wolves, wild and undomesticated and completely lacking in urban sensibilities.

In Egypt, the pharaoh played a role similar to that of the Mesopotamian king, ruling a divinely organized realm and entrusted with the task of keeping all chaotic forces, in the form of wild animals and uncivilized foreigners, at bay. The land of Egypt was understood as reflecting *maat* (order), and all its inhabitants, from the pharaoh to his humblest subjects, were expected to fulfill their divinely ordained roles and maintain this order. The pharaoh's military triumph over external and hence chaotic enemy polities was thus imbued with cosmic overtones and was often depicted in temple and palatial contexts. Indeed, these scenes may even have served an apotropaic (to ward off evil) function, protecting the structures they adorned from chaotic human or supernatural influences in the same manner as the pharaoh protected Egypt from its enemies.

The identification of foreign polities with the forces of chaos, which had to be conquered

➤ DIVINE CHAMPIONS OF ORDER

The king's role as the guardian of order in Mesopotamia mirrored the role of various divine warriors, including Ningirsu, Ninurta, Marduk, and Ashur. Ninurta, who was eventually syncretized with Ningirsu, served as the gods' champion in the Anzu myth, recovering the Tablet of Destinies stolen from the god Enlil by the monster Anzu and thus restoring the cosmic order. In the later *Enuma Elish* myth, the Tablet of Destinies was bestowed upon an unworthy deity, Qingu, by the goddess Tiamat. It was recovered in the Babylonian version of the myth by the god Marduk and in the Assyrian version by the god Ashur.

—Karen Sonik

and dominated by the pharaoh, does not accurately represent Egypt's often quite practical foreign policy but instead seems intended to satisfy internal ideological requirements. From the fourteenth century to the twelfth century especially, Egypt interacted with the powerful polities of the ancient Near East, including Mitanni, Babylon, and the Middle Assyrian empire, as equals.

Was There War in the Indus Civilization?

Warfare seems to have been a feature of all early civilized societies except, it would appear, the Indus civilization. Early excavations in the Indus cities yielded no evidence of warfare or defense, and the Harappans were regarded as peace-loving people. However this view was overturned in the 1940s when Sir Mortimer Wheeler started investigating the Indus civilization.

Wheeler had fought in both world wars, and his distinguished archaeological career had been largely concerned with the warlike Romans. He therefore looked for and believed that he had found evidence of Harappan militarism. At Harappa, Wheeler interpreted the AB mound as a fortified citadel, a view apparently confirmed when excavation revealed remains of a massive mud-brick wall with towers and impressive gateways. At Mohenjo-daro, Wheeler also uncovered solid brickwork including towers, convincing him that this city too had a fortified citadel.

More recent excavations have confirmed that other Indus towns and cities were also surrounded by massive walls constructed of baked bricks, mud brick, rubble, or stone, particularly around one part of the settlement, often elevated, generally known as the citadel. The city walls at Dholavira, for example, were 19.6 yards (18 meters) wide and at least 9.8 yards (9 meters) high. Some were retaining walls for mud-brick platforms, others were freestanding circuit walls, and some were both: for example, the wall around Harappa mound E was a revetment in the northwest of the mound but a freestanding wall around its south. Frequently there were bastions and sometimes towers, and there were generally imposing gateways.

Closer examination suggests that these were not military defenses. The most critical point in a fortification wall is the gateway, which must be designed to allow those inside to attack an approaching enemy while protecting themselves against enemy attack. The design of Harappan gateways did not reflect such military considerations. They were generally a straightforward opening or passage, although strong wooden gates would have allowed them to be closed. Side chambers often flanked the gateway, probably

accommodating gatekeepers who could monitor the flow of people and perhaps collect taxes or customs dues on goods being taken in or out. The walls also demarcated and separated the principal areas of the settlement, particularly the citadel on which were located important public buildings.

The elaboration of Harappan gateways seems designed to increase the impressiveness and solemnity of the approach rather than to facilitate defense. For example, at Dholavira the main gateway to the citadel opened from a terrace approached by a long ramp; two chambers flanked the passage through the gateway, each fronted by pillars on stone bases. A wooden signboard was probably originally set above the gateway.

Another significant nondefensive feature is that there were often several ways into the walled area: the impressive gateway that controlled and could bar access and another more simple entrance. This is exemplified at Kuntasi in Saurashtra. Its double wall of boulders and mud was separated by a passage 21.8 yards (20 meters) wide. In its southwestern corner was a tower, and on the east side there was a gate flanked by guard chambers, the impressive entrance for visitors to the walled town. In contrast, a small postern gate in the northern wall provided easy access for residents of the town's unwallled suburbs.

Many settlements were walled, and a number were wholly or partly founded on artificial platforms of mud brick, earth, and rubble with substantial retaining walls. These required enormous amounts of materials, time, and labor (calculated at around four million man-days for Mohenjo-daro). Rather than being military fortifications, a better explanation for the massive walls and platforms is defense against the annual floods, whose extent and violence were unpredictable. Flood damage has been reported at several Harappan sites, confirming that flooding was a significant hazard. The enormous platforms at Mohenjo-daro, more than 6.5 yards (6 meters) high, raised the city above any possible floodwaters.

Wheeler noted that many Harappan artifacts, such as arrowheads, spearheads, axes, and daggers, could have been used as weapons, although he also admitted that they could have served

other purposes such as hunting, an activity that was important to the Harappans. The guardrooms flanking the gateway at Kuntasi contained clay slingshot; however, these were also found in the village of Kanewal, where they were probably used against wild animals. Absent from the Indus sites are any objects designed specifically for warfare, such as helmets, body armor, or shields.

Examination of the few hundred known Harappan burials has revealed only one skeleton with signs of death from physical damage: a man from Kalibangan who suffered a fatal knee injury, quite possibly accidental.

The Harappans were exceptional in lacking a natural enemy. Other civilizations were constantly threatened by nomads from neighboring hills and deserts, aggressive adjacent states, or internal friction over access to limited agricultural land or water for irrigation. The Harappans, in contrast, had shared ancestry with the people on their western border with whom they maintained good relations. These well-disposed highland cultures provided a buffer between the Harappans and their nearest civilized neighbors, the Helmand culture, and the mountains themselves were a deterrent to armed invasion from the Iranian plateau.

Within the Harappan realms the diversity of resources and economic potential between the different regions and the great productivity of its lands and relatively low population density meant that there was no spur to internal conflict and that there were considerable benefits to be gained from cooperation between the inhabitants of the regions. Population density in other neighboring regions, such as the Aravallis, was even lower and the benefits of peaceful cooperation even greater given the relative technological levels of the Harappans and their neighbors. The sea to the south was the only potentially hostile border. However, Harappan shipping probably commanded the sea-lanes, and the people of the nearest landfall, Magan (Oman), were in friendly collaboration with the Harappans.

It would seem therefore that the Harappans were not subject to external threats, while nothing in the neighboring regions attracted them to use coercive or acquisitive force: adjacent lands were not agriculturally attractive, and it was

➤ THE MOHENJO-DARO "MASSACRE"

Excavations in the upper levels at Mohenjo-daro uncovered many skeletons in the streets and houses in several parts of the city, with clusters of up to 13 haphazardly sprawled skeletons. Mortimer Wheeler, with characteristic narrative zeal, linked all these to a single cataclysmic event, the fall of the city to Aryan invaders and the massacre of its inhabitants. Wheeler's persuasive writing has led to a wide acceptance of this tale.

Like so many good stories based on insufficient data, this one has fallen apart under scrutiny. For a start, although the skeletons were all from late contexts, they were not all contemporary, so their deaths do not relate to a single event. Only two of the supposed victims had signs of physical injury, and in both cases the injury had healed months before death. Instead, most seem to be individuals buried in a perfunctory fashion in abandoned houses or disused streets in a period when civic society was breaking down. Analysis of the bones shows that many individuals had suffered from malaria, and it is possible that cholera was also rife. Disease probably contributed significantly to the collapse of urban life at Mohenjo-daro; there is no evidence that invaders from outside played any part, either at Mohenjo-daro or elsewhere.

—Jane R. McIntosh

economically more efficient to trade with their neighbors than to take direct control of procuring resources such as the copper of the Aravallis.

There is one possible exception to this absence of warfare. In the enigmatic Transition period (2600–2500 BCE) more than three-fifths of Early Indus settlements were abandoned, and many were destroyed by fire. Only a few were replaced by new settlements in the same location. Instead, there were a great many new foundations. An important exception was Harappa, which, far from being abandoned, enjoyed continuous development from the fourth millennium into the Mature Harappan period, during which features characteristic of the Indus civilization gradually emerged.

The fiery destruction at many sites has been interpreted by some scholars as evidence of warfare. However, there is no other supporting

evidence, such as weaponry or dead bodies within the destroyed settlements.

An alternative explanation is that the deliberate destruction of old settlements and the creation of new settlements following certain principles, such as the cardinal orientation of streets and the emphasis on water supply and sanitation, reflect the widespread adoption of a new ideology that was to underlie the unity and considerable uniformity of the Indus civilization. In this scenario, rather than indicating enemy action, the destruction by fire of the settlements would be an act of ritual or ideological purification.

The Zhou Conquest of the Shang and the Consolidation of Empire

In 1045 BCE the army of the Western Zhou defeated the Shang army at the Battle of Muye. Later commentators took the defeat of the Shang by the Zhou as a mandate of heaven in which the gods removed the right to rule from the Shang kings and bestowed it upon the kings of the Western Zhou. The defeat of the Shang at the Battle of Muye proved to be one of the most formative battles in the antiquity of China, ushering in the Zhou era.

Prior to the Battle of Muye, Western Zhou kings had been consolidating their authority in the region of the Fen River to the west of the Shang capital, Anyang. These battles did not bring the Zhou directly into conflict with the

Shang kings; rather, battles in these regions were against Shang allies or cities outside of the Shang sphere of authority. However, when King Wen of the Zhou (r. 1099–1050) defeated an army on the Qin River, the Zhou army lingered near the natural defensive boundary of the Shang kingdom. Wen, however, did not directly attack the Shang. He continued to define his authority in this western region until he died in battle in 1050.

With King Wen's death, his son King Wu came to power, bringing with him a new strategy for military conquest. Wu now directed hostilities at the Shang state, creating a coalition of anti-Shang forces at the fjord of Menjin in 1048. Tradition holds that this coalition consisted of 800 local lords; likely this number is exaggerated, but the hierarchical coalition that Wu created is consistent with later Western Zhou governance. With this force Wu did make an incursion into the central plain (the Shang heartland) but retreated without engaging in a major offensive.

The major offensive came in 1045. According to the *Shi ji*, Wu led a force of 45,000 men and 300 chariots toward Anyang from the south. Shaughnessy has argued that this was a strong tactical movement since the Shang defensive forces were located in the Taihang Mountains, protecting against an incursion from the west. Wu's army met the Shang army at Muye, south of Anyang, the location of the Shang King Di Xin's capital. The battle, in which the Zhou army was victorious, is described in the *Shi ji*. King Di Xin was not captured; he committed suicide. Other members of the Shang aristocracy and government were either dispatched or incorporated into the Zhou governmental structure.

The Battle of Muye did not result in a complete consolidation of the Western Zhou kingdom. The weaknesses in the Zhou state became apparent when a dynastic struggle ensued after the death of King Wu in 1043. The Duke of Zhou, who declared himself regent along with the adult King Cheng (son of Wu), retained control of the Zhou kingdom. On the eastern periphery other relatives of Wu joined forces with Shang leaders who had not yet been routed or incorporated into the Western Zhou kingdom. The Duke of Zhou and King Cheng led a campaign against the rebellious forces in the east and within two

years had extended the Western Zhou kingdom to the east coast of China.

Antiwar Sentiments in Zhou Poetry

The Chinese era of philosophers in the middle of the first millennium BCE is well known for sages, such as Mozi (Mo-tzu), advocating peace and the restoration of harmony. Even before this time, Zhou (Chou) poetry often expressed antiwar sentiments including being weary of war and the sufferings that accompanied warfare, conscription, and prolonged separation from loved ones. The *Classic of Songs* (*Shi jing*) is the earliest anthology of Chinese poetry and includes a number of examples of this war-weary attitude. This highly revered collection includes 305 poems gathered from a vast array of folk songs, hymns, and poetic descriptions of life at court and among common people from primarily the ninth through seventh centuries BCE. The songs were compiled at the end of this time period, but many themes and images are rooted in earlier folk tradition. Although traditional Chinese accounts attribute the *Shi jing*'s compilation to Confucius and count it among the core Five Confucian Classics, it is evident that it had been collected before the time of Confucius, who made reference to this anthology in his *Analects*. The following passages are from Arthur Waley's translation of the *Book of Songs*. Each verse listed below is followed by the Mao number, which identifies the song according to the dominant order for songs in the collection. This order, which

was established more than 2,000 years ago by two editors named Mao, corresponds to the four divisions of song types: *Airs of the States*, *Lesser and Greater Elegances*, and *Hymns*.

"Minister of War,
We are the king's claws and fangs.
Why should you roll us on from misery to
misery,
Giving us no place to stop in or take rest?

. . . Minister of War,
Truly you are not wise.
Why should you roll us from misery to misery?
We have mothers who lack food." (185)

This poem includes direct political critique as well as typical expressions of soldiers' woe, where their own misery is compounded by the knowledge that they cannot look after family members and obligations at home. Another poem uses imagery from the natural world to bemoan the unnatural state of forcibly conscripted soldiers, who were ripped from their homes and families to be treated in a subhuman manner.

"What plant is not faded?
What day do we not march?
What man is not taken
To defend the four bounds?

What plant is not wilting?
What man is not taken from his wife?
Alas for us soldiers,
Treated as though we were not fellow-men!

Are we buffaloes, are we tigers
That our home should be these desolate wilds?
Alas for us soldiers,
Neither by day nor night can we rest!" (234)

This idea of the hardship of living and dying in desolate wilds is common to later Chinese literature as well and can be found in a poignant poem written by Han Yu during his brief exile in the ninth century CE, where he laments the prospect of dying in the wild borderlands far from the capital, palace, and civilization he had sought to protect. However, it is the references

► POLITICAL READINGS OF ANCIENT CHINESE POETRY

The *Shi jing* can be translated as the Classic Book (*jing*) of Songs, Poetry, and Odes (*shi*). Shi, rather than referring to poetry as a whole, is a specific poetic form dominant in early Chinese poetry and influential until modern times. The English title, *Classic of Songs*, usefully emphasizes that most or all of the 305 poems in this collection were set to music. Although the music has been lost, Confucius and others have emphasized the importance of music, and one can better understand and appreciate these poems by recognizing that they were lyrics as well as poetry. This is not only the oldest anthology of Chinese poems and songs; it also served as the template for more than 2,500 years of this especially influential shi form, known as classical poetry. Scholars such as Victor Mair have indicated that these poems were variously understood by Confucius and his followers as “a canonical collection of important moral truths and lessons,” a “guide for moderation in speech and

action,” and “a detailed chronicle of praise of the heroes and heroines or blame of the villains of early Chinese history.” However, during the later Sung dynasty, a “reaction against such historical and political explications” of these poems emerged, and instead a view that the poems were “folk songs devoid of political intent and historical judgment” prevailed. Even without political readings, the different types of poems in this collection offer insights into the daily lives and concerns of Chinese people from the Zhou era. The poems remain relevant and influential, but as with other literary forms, they are open to multiple interpretations.

to being taken from one’s wife and marched without rest that resonate most fully with the antiwar sentiments in Zhou poetry. In one example of the perils of being separated from family by military obligation, Waley notes that the imagery and theme of a poem that ends with “This new marriage is very festive; But the old marriage, what of that?” indicates “that during the soldier’s absence his wife has assumed his death and married again.”

A poem from a military campaign circa 800 BCE reinforces sentiments of weariness and the unpredictable length of military service at the whim of the king’s commands. The king is referred to as Son of Heaven, indicating the Zhou concept of divine and natural sanction for the king’s political authority. In the following poem, the suffering soldiers are described as fearing the “writing on the tablets” (the king’s next command) rather than criticizing or challenging the king directly.

“Long ago, when we started,
The wine-millet and cooking-millet were in
flower.
Now that we are on the march again

Snow falls upon the mire.
The king’s service brings many hardships.
We have no time to rest or bide.
We do indeed long to return;
But we fear the writing on the tablets.” (168)

Another poem from the *Shi jing*, this one translated by Burton Watson, uses natural imagery of agricultural seasons to indicate the excessively long military service and to suggest what the soldiers are missing at home. These soldiers place some of the blame for their predicament on the Hsien-yun tribes against whom they are guarding the border, as opposed to the political criticism of their own war minister in the first poem cited above.

“We pick ferns, we pick ferns, for the ferns are
sprouting now:
Oh to go home, to go home before the year is
over!
No rooms, no houses for us, all because of the
Hsien-yun, no time to kneel or sit down,
all because of the Hsien-yun.
. . . Our hearts are saddened, our sad hearts
smolder and burn.

We are hungry, we are thirsty, no limit to our
border duty, no way to send home for news.
... oh to go home, to go home in the closing
months of the year!
The king's business allows no slacking, no
leisure to kneel or rest.
Our sad hearts are sick to death, this journey of
ours has no return!
... Long ago we set out when willows were
rich and green.
Now we come back through thickly falling
snow.
Slow slow our march, we are thirsty, we are
hungry, our hearts worn with sorrow, no
one
knows our woe." (167)

These poems illuminate aspects of Chinese life almost 3,000 years ago in an easily accessible medium, which has long been valued in China as a means for communicating a wide range of experiences and expressions including these antiwar sentiments that often include messages critical of social or political injustice along with bemoaning soldiers' hardships and the pain of separation.

■ Introduction: Egypt and Its Enemies

Ancient Egypt was relatively isolated. Deserts along either side of the Nile River valley kept the region relatively safe from invaders. Two fronts, however, posed intermittent problems to the Egyptians: Nubia and Syria-Palestine. To the south was Nubia, in what is now called the Sudan. Even though the Nile runs through Nubian territory, cataracts along the river made navigation difficult and acted as a natural barrier between the two regions. Although difficult to navigate, travel between Nubia and Egypt was not impossible, and relationships between the two regions vacillated between friendly and hostile.

To the northeast was Syria-Palestine. This territory lay as the land route that connected Asia and Africa (now separated by the Suez Canal) and was thus of vital strategic importance. The Egyptians were occasionally troubled by attacks from this front. However, for much of Egyptian history this was an area that was governed by the Egyptians as part of their empire. Rule over this region was never secure, as the various accounts of military engagements in the region attest. Arguably the most noteworthy conflict in this region during Egypt's New Kingdom was with the Hittites of Anatolia. Hostilities culminated in the Battle of Kadesh (Qadesh), which

resulted in the first known mutual peace treaty between two powerful states. This battle is dealt with in detail at the end of this section.

Egyptian incursions into both fronts were motivated by a number of factors. Ancient texts cite concerns with the security of the Nile floodplain as motivations for taking an aggressive stance in both of these regions. Resource acquisition must also have been a motivator. Nubia was rich in mineral resources, especially gold. Syria-Palestine was rich in many products, most notably timber, which is not readily available in Egypt.

—Kevin M. McGeough

Egypt and Nubia— Cataract Fortresses

The most decisive endeavor in the history of Egypt-Nubia relations was the construction of an impressive system of strategically placed fortresses in Nubia. Although walled fortified structures were known from most periods of ancient Egyptian history, the fortress network developed by the Twelfth Dynasty of the Middle Kingdom was the most intensive investment in such military apparatus. Three primary objectives were served by these military structures: to guard Egypt's changing border with its southern neigh-

View of the Nile from the fort at Buhen, Egypt. (Roger Wood/Corbis)

bor Nubia, controlling northward passage of Nubians; to protect Egyptian mining projects and trade routes; and in regions where Nubian populations concentrated, to monitor their movements and control uprisings against the occupying Egyptian personnel.

Although in the Old Kingdom a fortified industrial operation was situated at Buhen, in general Egyptian occupation of Nubia was limited to periodic raids and expeditions to areas of natural resources and for trade with more southerly regions of Africa. Senwosret I initiated the first major development, setting forts to encompass a frontier in the Buhen region north of the Second Cataract, where one of the better-studied forts (at Buhen itself) was located. Later in the dynasty, Senwosret III was quite aggressive in Nubia, pushing southward to take control of the entire Second Cataract region and, in addition to upgrading old forts, founding several new ones between the Second and Third Cataracts. This program effectively created a buffer zone between Egypt's hold on northern Lower Nubia and the emerging power of the Kushites near the Third Cataract at Kerma.

Fortresses located on the flat desert areas adjacent to the Nile were often rectangular in shape.

► COORDINATING THE FORTRESS SYSTEM—THE SEMNA DISPATCHES

Some cataract fortresses were centers of trade, while others acted as supply stations to provision other forts. The Semna Dispatches indicate that Nubians were permitted past the frontier zone for purposes of trade or other official business. This series of eight reports from the late Twelfth Dynasty were filed together at Thebes. They implicate meticulously coordinated communication among forts. Each account records the date and circumstances of Nubian encounters, whether for trade or for interrogation after intercepting them in the nearby desert. Patrols also reported if they discovered traces of local activity. After conducting business, merchants were provided with a meal and were sent back to their home regions.

—Nicholas S. Picardo

In rugged, uneven areas such as islands and natural coastal outcroppings, irregular shapes ranged from vaguely triangular (e.g., Uronarti and Shalfak) to even L-shaped (e.g., Semna), custom fitted to the terrain to maximize defensive potential. Often fort pairs flanked opposite sides of the waterway to create squeeze points. Most would have had harbors for river access during the annual flood. State foundations of all types had symbolic names that expressed and magically contributed to their functions. For example, two forts in the Second Cataract region received names of That-Which-Repells-the-Medjay (a Nubian group) and That-Which-Opposes-the-Bows.

The defensive nature of the Nubian fortresses is clear in their intricately conceived design. Massive buttressed walls of mud brick, 9 feet (3 meters thick) and reinforced by wooden beams, could enclose areas from just over 32,000 to more than 645,000 square feet (3,000 to 60,000 square meters). Troops could sometimes line up along built-in ledges and wall projections to defend most exterior facades from behind the protection of a defense wall. Interspersed along some exterior walls were angled slits through which archers could fire at attackers while still shielded. Surrounding combinations of ditches, dry moats, and embankments combined with secondary external defense walls and watchtowers as formidable obstacles to enemy forces attempting to get close enough to be a threat. Spur walls sometimes jutted out abruptly from the perimeter walls at various intervals to extend the range of insulated combat. Covered stone passages and stairways led from fort to river to permit access to water even if penned in by attack.

Egypt's hold on Upper Nubia eased with the decline of the Middle Kingdom. However, lasting communities had been established at fort sites by this time. So, although state sponsorship waned, many fortresses show occupational levels to the New Kingdom when reestablished Egyptian presence in Nubia was of a different nature. Final destruction likely followed into the New Kingdom. The construction of the Aswan High Dam through the late 1960s CE formed Lake Nasser, under which the Nubian fort sites were submerged and lost to archaeology.

Middle Bronze Age in Syria-Palestine

The Middle Bronze Age (MBA, ca. 2000–1550 BCE) was a period of resurgence of urbanism in Syria-Palestine following the urban collapse at the end of the Early Bronze Age (EBA). It was roughly contemporaneous with the Isin-Larsa and Old Babylonian periods in southern Mesopotamia, the time of Shamshi-Adad and the Old Assyrian colonies in northern Mesopotamia, and the Middle Kingdom and Second Intermediate period in Egypt.

The political situation during this period can be generally characterized as the coexistence of a number of individual city-states, each controlling its hinterland. Urban planning was sophisticated, revealing a high level of social complexity. In some cases larger kingdoms developed, such as Yamhad (centered at Aleppo), Qatna, and Hazor. These various polities both cooperated with and rivaled each other; warfare was a constant reality, as witnessed by the ubiquity of walled fortifications during this period. Many of the MBA cities were built on the ruins of urban sites that had been abandoned at the end of the EBA.

The MBA brought with it significant technological changes in a number of areas, including ceramics, metallurgy, and fortifications. In ceramics, the use of the fast wheel led to a change in pottery shapes and designs. Moreover, tin bronze began to replace copper as the primary metal for making weapons and tools. In the area of urban defense, the building of massive earthen ramparts in many sites in the southern Levant (Palestine) continued traditions of fortification

THE AMORITES

The term “Amorite” comes from the Hebrew Bible, where it refers to one of the groups of peoples living in Canaan before the Israelites entered the land. However, in modern scholarship, it is either used as a catch-all term for the tribal-based peoples with West Semitic names who take over the leadership of most major centers in Syria and Mesopotamia in the first half of the second millennium BCE or to designate the linguistic entity represented by these proper names. The association of Amorites with nomadic pastoralism is discernible from vocabulary in the Mari texts as well as from characterizations of people designated as *martu* (Sumerian) or *amurru* (Akkadian)—both translatable as “Westerner(s)” —in other cuneiform sources. Earlier scholarship took for granted the idea of a nomadic Amorite invasion sweeping across the Near East in the early second millennium BCE, taking their cue from portrayals of Amorites as hostile raiders in southern Mesopotamian texts. However, more recent investigations have emphasized the dimorphic (pastoralists and sedentarists living in mutual dependence) nature of ancient Near Eastern society; the ascendancy of the Amorites was probably a complex process involving gradual infiltration followed by the assumption of leadership during a time of political instability in the early second millennium.

—Joseph Lam

found earlier in the north (Syria); these in turn may have been in response to improved technologies in warfare, such as the composite bow and the battering ram. One further technological innovation, profoundly significant in terms of world history, was the invention of the alphabet: it was toward the end of the MBA that the first signs of alphabetic writing (the so-called Proto-Canaanite and Proto-Sinaitic inscriptions) began to appear in Palestine.

International relations played an increasingly important role in the MBA. All major MBA urban settlements were located close to major trade routes, either land or sea. This is partly connected to the use of tin bronze, requiring the im-

porting of tin from areas such as Anatolia and Afghanistan. In the north where textual documentation was more abundant, we find power struggles among the various Amorite kingdoms (i.e., kingdoms ruled by people with West Semitic names) of Syria and Mesopotamia. A major source for these political developments is the Mari tablets, which reveal tensions between Yamhad and the Upper Mesopotamian kingdom of Shamshi-Adad. During this time, we also find increasing evidence (mostly from proper names) of the presence of another group, the Hurrians, in northern Mesopotamia and Syria.

The fortunes of Palestine, on the other hand, were closely tied with those of Egypt. Unlike the succeeding Late Bronze Age in which Palestine experienced direct Egyptian political domination, the MBA was characterized more by economic interactions between the two regions. The city of Byblos on the Mediterranean coast, as a major seaport for trade with Egypt, is a case in point. Excavations there have revealed a wealth of objects associated with Middle Kingdom Egypt. A number of other Egyptian artifacts provide information on relations between Palestine and Egypt in the MBA. The Execration Texts, which are bowls and statuettes containing inscriptions of people and place names considered enemies of Egypt, give us valuable geographical information as well as insight into the level of Egyptian knowledge of Palestine during this period. The Story of Sinuhe, a Middle Kingdom prose text, sheds considerable insight on the details of everyday life in the northern Levant. A wall painting (ca. 1890 BCE) found at Beni Hasan depicts a caravan of West Semites headed to Egypt, providing evidence of such migrations early in the MBA.

The issue of southward migration relates to the phenomenon of the Hyksos. This term, coming from an Egyptian phrase meaning “rulers of foreign lands,” denotes a group of Semitic peoples who took political control of Egypt during the Second Intermediate period (ca. 1650–1550 BCE) but were subsequently driven out by Ahmose, who became the first king of the Eighteenth Dynasty. It is now recognized that the Hyksos’ rise to power was the culmination of a long process of migrations of foreigners to Egypt

throughout the MBA. Key archaeological evidence for this comes from the site of Avaris (present-day Tell el-Daba) in the Egyptian delta, which was the capital of the Hyksos rulers; excavations have revealed a material culture with strong connections to that of southern Palestine.

Hyksos

Hyksos is the Greek rendering of the Egyptian word for “rulers of foreign countries” and should not be confused with the popular yet false etymology of “Shepherd Kings” promulgated by Josephus. While the term was originally used to designate any foreign rulers, in time it came to refer specifically to the Fifteenth Dynasty. The kings of this dynasty were of Near Eastern origin and ruled Egypt in a syncretistic fashion, mixing both Levantine and Egyptian practices. After approximately 100 years of ruling Egypt, they were expelled by native Egyptians and retreated back to lower Palestine.

The Hyksos capital, ancient Avaris, has been identified with modern Tell el-Daba. The careful excavations of an Austrian team led by Manfred Bietak have done much to help us understand the origins of the Hyksos. Avaris experienced a steady influx of Semitic peoples during the Twelfth and Thirteenth dynasties, consisting of a mix of merchants and warriors. It is quite likely that Avaris’s growth was connected to the seafaring abilities of the Phoenician coastal inhabitants and stemmed from its harbor’s value to maritime trade. Cultural remains, such as houses, burials, and pottery, demonstrate that the immigrants were from northern and northeastern Syria. Just before the advent of the Fifteenth Dy-

nasty and the subsequent takeover of Egypt, there was a sudden influx of peoples from southern Palestine.

The exact method of the Hyksos accession to kingship is not certain. Egyptian tradition holds that it was a military takeover. There is meager archaeological evidence supporting this, leading many Egyptologists to conclude that it was either largely political or economic in nature or a mixture of economic, political, and military means that led to Hyksos domination. Whatever the method of their assumption of power, the Hyksos employed Egyptian officials and adopted much in the way of Egyptian ruling traditions and titular trappings while maintaining Levantine methods as well, such as ruling the differing sections of Egypt (and probably southern and coastal Palestine) in a manner that approximated the traditional Near Eastern vassal system of rule. The Sixteenth and Seventeenth dynasties were likely contemporary vassal dynasties representing differing portions of Egypt whose rulers were beholden, to differing degrees, to the Hyksos kings.

It is difficult to make a one-to-one correspondence between the names of Hyksos rulers provided to us by Manetho and those who are archaeologically attested. Both Manetho and the Turin Canon list six Hyksos kings, all of whose names seem to be West Semitic. Of these, significant archaeological remains are known for two. Seuserenre Khayan, who is probably Manetho’s Apachnan, engaged widely in monumental building and also usurped a number of Middle Kingdom statues. The best-known and probably the most powerful Hyksos king was Apophis (Apepi), who reigned for about 40 years.

The Hyksos engaged in intense trade with southern Palestine and Kush (Nubia). They also regularly exchanged goods with other areas around the Mediterranean, including Cyprus and Crete.

Empire of the New Kingdom

Throughout the New Kingdom period (ca. 1570–1070 BCE), Egypt exercised a degree of military, social, and economic influence in Nubia to the south, Syria-Palestine to the northeast, and, to a far lesser extent, Libya to the west. Initially, Egypt's imperial ambitions may have been a response to the immediately preceding period of domination by the foreign Hyksos rulers. Egypt was determined to be free of any such foreign rule and made attempts to secure its borders and extend its sphere of military influence. The king's office embodied the notion of the preservation of Egypt's borders. His perceived success at maintaining and extending the empire was directly related to his success at home. The Hyksos wars had also provided an outlet for a military class, who would have benefited socially and economically from ongoing warfare throughout the New Kingdom period. Other factors would also have played a role in the ongoing motivation for empire. Imperial expansion provided Egypt with access to particular commodities not readily available at home; control of profitable trade routes, especially to the northeast; and a buffer zone against other large empires.

The nature and extent of Egypt's imperial influence in the three regions differed considerably. In Nubia, the Egyptians adopted a deliberate policy of Egyptianization. They imposed a full-scale Egyptian administrative bureaucracy, built Egyptian-styled temple-centered towns, took the children of the Nubian elite back to Egypt for education and acculturation, and implemented Egyptian agricultural technology in the region. In effect, Nubia became a province of Egypt.

In Syria-Palestine, Egypt adopted a different policy. There, a complex system of independent city-states, each with its own petty king, had already existed. Egypt exploited this system and adopted a vassal-suzerain relationship with the Canaanite rulers. This system of rule was influ-

enced by the presence of the larger empires of Mitanni and Hatti farther north with whom Egypt competed for the loyalty of individual city-states. The archive of fourteenth-century BCE texts found at Amarna contains diplomatic correspondence between these Canaanite rulers and their Egyptian overlords. It allows us a glimpse into Egypt's policy of also pitting these states against each other. As part of its control of the region, Egypt maintained a number of fortresses along the Way of Horus from the eastern Delta, through northern Sinai, and on into southeastern Palestine. However, it is not clear to what extent there was any substantial permanent Egyptian presence in Syria-Palestine itself. Egyptian kings periodically campaigned in the region. Among these was Ramses II, who fought the famous battle of Kadesh against the Hittites. Beginning with Thutmose III's defeat of a coalition of Syrians at the city-fortress of Megiddo (ca. 1457 BCE), imperial policy in the region also included taking the children of vassal kings back to Egypt as hostages where they were educated and acculturated. During the Nineteenth Dynasty, there is a sharp increase in the presence of Egyptian buildings and artifacts in Syria-Palestine. It appears that there was some shift in Egyptian policy toward the region at this time. Egypt may have begun to assume more direct political control of the region or at least the economic burden of maintaining the governance of the region.

The Libyan tribes had always posed a minor threat to the Egyptian western Delta, and in the reign of Ramses II, a series of fortress towns was constructed to secure Egypt's western border. Ramses III made an ill-fated attempt to appoint a Libyan ruler of his choosing to govern these western tribes. However, Egypt never exercised the kind of influence in Libya that it did in Nubia or Syria-Palestine. The west remained a border to be defended rather than a potential new zone for Egyptian imperial expansion.

At the end of the Late Bronze Age, Egypt was one of many Mediterranean empires to suffer collapse. The reasons for this widespread collapse remain obscure. It may have been due to large-scale migrations into the region, a catastrophic infectious disease, an environmental catastrophe leading to widespread famine, or changes in the

➤ BATTLE OF MEGIDDO

The Battle of Megiddo is considered to be the earliest historical battle, meaning that it is the first for which the date, location, and events of the battle are known. Having more information allows scholars to assess the events with greater certainty. The battle was fought in the spring of about 1480 BCE near the ancient site of Megiddo in the Jezreel Valley in what is now northern Israel. The city of Megiddo was an important location, as it controlled the major military and trade routes north to Lebanon and east to the Euphrates River region.

Possibly due to the encouragement of the ancient empire of Mitanni (what is now eastern Turkey and northern Iraq), a coalition of Canaanite and Syrian states rebelled against Egyptian rule and took control of Megiddo. The Egyptian pharaoh Thutmose III, in the first year of his reign (ca. 1504 BCE), led his forces to Megiddo to reclaim it. In a daring and dangerous tactical move, he led his forces through the pass at Aruna where the soldiers and horses would have to pass single-file through the gorge, while the chariots had to be carried by the charioteers. If Thutmose and his forces had been seen, the enemy forces could have destroyed them in the narrow confines of the gorge. The Egyptian forces were not discovered, and this allowed them to arrive at the plain beside Megiddo more quickly than had been expected

and effectively appear between the two halves of the coalition forces led by the king of Megiddo.

Thutmose III deployed his army in three sections. The Northern Division was positioned to the northwest of Megiddo, the Southern Division was located to the south of the city, and a smaller group was in the center (including the chariots and Pharaoh's royal bodyguard) and was commanded by Thutmose III himself. The battle began with a forceful charge that broke the morale of the coalition forces, who fled to the safety of the city. The Egyptian forces laid siege to Megiddo for seven months before the coalition forces surrendered. This battle benefited Thutmose III and Egypt, as Canaan was relatively peaceful for most of the next 20 years.

military tactics employed by subjugated peoples. It is likely that by the end of the Late Bronze Age the social and economic systems of these empires were at such a straining point that even some small shifts in any one of a number of factors could have had widespread repercussions, leading eventually to the collapse of empire. In later times, Egypt occasionally sought to exercise some influence in the political life of Syria-Palestine, but it never again achieved anything approaching its New Kingdom empire.

Egypt and the Hittites

The Late Bronze Age witnessed the rise of two major powers in the Near East, the New Kingdom Egyptians and the Hittites in Anatolia, destined to compete with one another for regional supremacy. Their battleground was Syria, Lebanon, and Palestine, and they fought for control of the Levant's impressive natural resources and access to important Mediterranean ports and islands, especially the copper on Cyprus. Ancient Syria was an important prize for the Egyptians and the Hittites. Both powers sent expeditions to the Syrian coastland to log the cedar, cypress, and pine of the Ammanus and Lebanon mountain ranges and sought access to the Syrian coastal cities whose sea lanes linked Anatolia, Mesopotamia, Egypt, and the Aegean.

The Hyksos invasion and conquest of Egypt in the seventeenth century BCE brought an end to the Middle Kingdom and introduced state-of-the-art military technologies from Mesopotamia to the people of the Nile for the very first time.

The Semitic-speaking Hyksos were originally from the Arabian Peninsula, moving into northern Mesopotamia, Syria, and Palestine in the first centuries of the second millennium BCE. The Hyksos infiltrated Egypt, dominating much of the region for nearly 100 years. During their occupation the Hyksos introduced new ways of making war to the Egyptians, including the horse-drawn war chariot, a heavier bronze sword, and the composite bow. Eventually, the Egyptians made use of these new martial technologies to throw off foreign domination, and under the Theban leader Amose I the Hyksos were expelled, and the Eighteenth Dynasty and the New Kingdom were founded.

During the period of the New Kingdom (ca. 1550–1070 BCE), Egypt became the most powerful state in the ancient Near East, expanding its borders south into Nubia, west into Libya, and northwest into the Levant. Palestine and Syria were occupied, and local princes were permitted to rule but under Egyptian suzerainty. At times, these client kings rebelled against their Egyptian landlords, precipitating military expeditions to deal with the uprisings. Often these wayward client kings sought assistance from the other hegemon in the region, the Hittites.

Ruling from their capital at Hattusas in central Anatolia, the Hittites grew at the expense of the Mitanni empire during the middle of the second millennium, emerging by 1400 BCE as the most powerful group in Turkey and rivaling Egypt as a regional power. During this period, the Hittites were almost constantly at war, either in order to claim territory from their neighbors or to protect their territory from other neighbors. The rise of a capable Hatti ruler named Suppiluliuma in the first half of the fourteenth century and his successful conquests of the Mitanni vassal states in Syria brought the Hittites to the attention of Thebes. After the Mitanni empire finally fell to the Hittites, the power balance in Syria switched in favor of the conquerors, and war between Egypt and the Hittites was inevitable.

The city-state of Qadesh on the Orontes River in Syria would prove to be the major source of friction between the Egyptians and Hittites. The king of Qadesh was a loyal vassal to Thebes and even took military action to block the advance

➤ HITTITES AND IRON

Modern scholars do not know precisely where ironworking began; however, both tradition and archaeological evidence point to ironworking developing in or near the longtime metallurgical heartland of the Bronze Age, the Anatolian plateau. Ancient historians and surviving contemporary documents associate ironworking with the Hittites, who flourished in Anatolia from about 1450–1200 BCE. The Hittites never used iron extensively, but they produced limited quantities of iron daggers and swords before their empire collapsed around 1200 BCE, exporting these precious weapons as gifts to neighboring monarchs in Assyria and Egypt. King Tutankhamen was buried with a Hittite dagger.

—Brian Todd Carey

of the Hatti south of his territory. But Qadesh's army was no match for the Hittite military machine, and the city was taken, precipitating unsuccessful military campaigns to recover this strategically important city by the pharaohs Akhenaten and Seti I. With a strong Hittite military presence in Syria, the balance of power shifted in the region, and soon other vassal states of Egypt fell to the Hittites without bloodshed. Seti's son and heir Ramses II (r. 1290–1224) would launch his own expedition in the fifth year of his reign (ca. 1285), culminating in one of the great battles of the ancient world, the Battle of Qadesh (also known as Kadesh).

The Battle of Qadesh

In 1285 BCE, the young Egyptian pharaoh Ramses II faced the expansionistic Hittites who had moved from their base in Anatolia into Syria. Ramses' target was the city of Qadesh on the Orontes River, and his goal was to end Hittite interference in the Egyptian sphere of influence in Syria by defeating the enemy's main force in the field.

Ramses' expeditionary army marched from Egypt to the city of Qadesh in one month. The Egyptian army contained 20,000 men, composed of four divisions of 5,000 each and some allied contingents. Each of the divisions consisted of charioteers, archers, spearmen, and ax-wielding infantry and were named after the gods Amun, Ra, Sutekh (Seth), and Ptah. Almost half the Egyptian force was comprised of 5,000 chariots. Defending the city of Qadesh was King Muwatallis II's Hittite army of 19,000 men and around 3,500 chariots.

On the morning of May 10, Ramses moved out at the van of the Amun division hoping to seize Qadesh by the end of the day. As the first elements of the lead division of Amun reached

Ramses II on his chariot at the battle of Qadesh, from a wall painting at Abu Simbel. (Pictorial Library of Bible Lands)

the forward camp, two newly captured Hatti scouts revealed under torture that the Hittite army was hidden to the east of Qadesh near the ruins of the old town of Qadesh. Before Ramses could react, the Hittite army quickly forded the Orontes from the southeast and struck the exposed right flank of the Ra division. The heavier Hittite war chariots pushed into the Egyptian files, killing and scattering the invading infantry. The Ra division broke in panic and fled up against the just-arriving Amun division, which routed as well.

The Hittite chariots pushed through the Egyptian column and swung to the northeast and pressed their attack on the western gate of Ramses' encampment. Although the lead Hatti units that penetrated the camp were dragged from their chariots by the pharaoh's bodyguard and killed, Ramses was unable to hold the fort. At this critical moment in the battle, he mounted his chariot and rushed forward without his bodyguard into the thick of the battle. Inspired by the courage of their pharaoh, a small force of Egyptian charioteers sallied forth from the east gate and, wheeling to the northwest, struck the Hittite flank while it was preoccupied looting the camp.

While the Egyptians began a concerted counterattack against the fleeing Hittite forces, King

► THE CHARIOT AT WAR

Egyptian chariots were served by a crew of two and were primarily firing platforms for archers and, accordingly, were light and flexible. The Hittite chariots encountered at Qadesh were heavier six-wheeled platforms crewed by three (a driver, shield-bearer, and soldier) and presumably designed for shock attack, a combat mode that required a sacrifice of speed and flexibility for combat survivability. But a new interpretation suggests that perhaps the composite bow was the primary weapon in Hittite chariots as well and that the heavier platforms were simply better-protected firing platforms and not moving battering rams.

—Brian Todd Carey

Muwatallis acted, committing his remaining 1,000 chariots to the battle. This relief force forded the Orontes north of Qadesh and swung south to hit Ramses in the flank. Unfortunately for Muwatallis, arriving from the north were reformed Egyptian troops, while the third of the Egyptian divisions, the Sutekh, approached from the south. Just as the Hittite chariots spread out onto the plain and into a line of attack, their right was threatened by the arriving rallied Egyptian forces from the north. To make matters worse for the Hatti king, Ramses broke off pursuit of the Hittite chariots trapped between him and the river and, joining forces with the Sutekh division, turned north to intercept the Hittite relief force. Caught between the two converging Egyptian armies, the Hittite relief force was destroyed. As the remnants of the first Hatti force escaped south of Qadesh across the Orontes, the final of the four Egyptian divisions, the Ptah, arrived on the battlefield too late to join the melee.

Tactically, the battle of Qadesh ended in a stalemate. Ramses withdrew from Syria, leaving the Hittites in Qadesh. Strategically, the Egyptians had failed in a major military operation to end Hittite influence in Syria-Palestine. Over the next two decades, the Hatti would instigate revolts in Palestine, forcing Ramses to respond with military action, but never again did the Egyptians threaten the Hittites north of the Orontes.

Eventually, these enemies became allies in the face of a new regional threat, the rise of Assyria in northern Mesopotamia.

The Peace Treaty between Egypt and the Hittites

The peace treaty ending hostilities between the warrior-pharaoh Ramses II of Egypt and the Hittite king Hattusili III was a novel document and the first of its kind in many ways in recorded history. Both of these regional powers had sparred over the riches of the Levant for centuries. The treaty eased tension over Syria by creating a clear border between the powers, although it ended Egyptian hegemony over the strategically important city-state of Qadesh. It also secured an alliance when both kingdoms were facing new strategic threats, specifically a resurgent Assyria in northern Mesopotamia and the rise of Libya in North Africa.

The turning point in relations between the Egyptians and Hittites was the Battle of Qadesh in 1285 BCE. Ramses won the battle but lacked the ability to seize the city, leaving the city-state to the Hittites. But the tactical stalemate did result in an opening of dialogue that would eventually result in a formal treaty, although the process was not without significant complications. After the death of the Hittite king Muwatallis, the throne in Hattusas in Anatolia was seized by Hattusili (later Hattusili III), forcing the prince regent Urhiteshub to seek exile in

Thebes in Egypt. Despite the presence of the Hatti prince, Hattusili and Ramses agreed to a peace treaty after two years of negotiations in the twenty-first year of the pharaoh's reign, or around 1270 BCE.

The treaty itself consisted of 18 articles, beginning with a long introduction exalting the two monarchs' titles and honors. These proclamations were followed by a pledge to end hostilities and establish a mutual alliance against foreign attack on either country and articles establishing a clause to intervene in the internal security of the other should the current regime be threatened by mutiny or coups. Ten articles were dedicated to the extradition of political refugees who sought refuge in the other's court. What made this most unusual is that the treaty did not exclude any person regardless of class. A fugitive seeking refuge was to be returned without being punished. The final articles invoked the major gods of both lands as witnesses to the treaty. The borders of the Egyptian and Hittite empires were not laid out in this treaty, although they were addressed in other documents.

Two copies of the treaty were recorded, one in Egyptian hieroglyph and the other in Akkadian. Both copies still survive and are identical except for their introductions. The Egyptian version states that it was the Hittite king Hattusili who requested peace, while the Hatti version has Ramses sending peace envoys. The Egyptian treaty was recorded on a silver plaque and then copied in stone at the large temple complex at Karnak.

To show good faith, gifts were exchanged between the monarchs, and both royal courts remained faithful to the spirit of the treaty, although friction did exist between Thebes and Hattusas. Despite articles of extradition, Ramses refused to return the exiled Hatti prince Urhiteshub to the Hittites, stating that he would not apply the treaty in retrospect. The exiled prince remained in Egypt for ten years. Possible complication arose in 1257 BCE when the Kassites in lower Mesopotamia began to court Thebes, but King Hattusili offered his daughter's hand in marriage to Ramses, and tensions eased after the union. In time, higher-level dignitaries were exchanged on a regular basis (including the Hatti prince regent visiting Thebes), and both great

Fragment of the Treaty of Qadesh, the agreement that ended the battle between the Hittites and the Egyptians for control of the Levant in 1275 BCE. (Carl Rasmussen <http://www.HolyLandPhotos.org>)

➤ THE FIFTY-TWO SONS OF RAMSES II

Perhaps the most powerful of the New Kingdom Egyptian pharaohs, Ramses II reigned for 67 years and must have been over 90 years old when he died. During his life he is believed to have fathered 52 sons by his several wives and concubines. Perhaps as many as 11 of these sons are buried in a tomb in the Valley of the Kings known to archaeologists as KV5. Partially explored in 1825 by English Egyptologist Sir James Burton, it was rediscovered in 1985 and represents one of the great finds of modern times. The two-level tomb complex consists of 150 chambers and corridors of which only 7 percent has been cleared, making KV5 one of the largest tombs ever found in Egypt.

—Brian Todd Carey

kings even met for a summit, with Ramses meeting the Hatti king in Canaan and escorting him back to Egypt. The personal relationship between these two monarchs helped forge an enduring peace, one that lasted until the fall of the Hittite empire.

■ Introduction: End of the Late Bronze Age

During the Late Bronze Age (ca. 1450–1200 BCE) the eastern Mediterranean world was characterized by strong city-states and dynastic empires. But at the end of the era there was widespread turmoil. Many cities were destroyed, never to be occupied again. The social and political fabric of the region was ripped apart, and there was a major shift in the political economy of the region.

Prior to the end of the period, the eastern Mediterranean was marked by strong urban centers that supported and were ruled by elites living in large palace and temple complexes. Many of the states were literate and kept economic records, diplomatic correspondence, and religious texts. Agricultural production supported the economy and involved some centralized control through taxation or tribute, as is evidenced by central storehouses in many of the large city-states. Centralization enabled specialized production of elite goods, as shown by finely crafted weapons, jewelry, figurines, and ceramic vessels. Bronze was the metal of choice for weapons and metal tools. Long-distance trade of all goods, from raw materials and agricultural products to luxury goods and fine ceramics, occurred throughout the region. Trade took place over long distances and likely involved networks of transactions and the work of specialized traders who used seaborne shipping routes around the Mediterranean Sea.

However, in a roughly 100-year period from about 1250 to 1150 BCE, the Mediterranean world of the Late Bronze Age experienced momentous change. Many of the city-states at the center of empires suffered major destruction, multiple times in some cases, leading to the eventual abandonment of the city or to resettlement on a

much smaller and poorer scale. Long-distance trade ended. Utilitarian goods dominated the material culture, and these were produced locally. Finely made luxury goods disappeared, and the decorative arts, especially as seen in ceramic production, became more crude and rough in style. There appears to have been a shift to less economic diversity and a greater emphasis on subsistence economic activities that concentrated on producing primarily agricultural products. One of the most significant changes was a slow but steady increase in the manufacture and use of iron as the primary metal for tools and weapons at the same time that there is a concomitant drop in the use of bronze.

—D. Bruce MacKay

Collapse of Mediterranean Trade

One of the dominant characteristics of the Late Bronze Age was trade of raw materials and manufactured goods all around the eastern Mediterranean. The cessation of this international trade is one of the key features that marks the end of the Late Bronze Age and the shift to the Iron Age.

Evidence for the networks of Mediterranean trade during the period comes from imported goods recovered in excavations around the region and from spectacular Late Bronze Age shipwrecks off the southern coast of Turkey near Cape Gelidonya and at Ulu Burun. Texts and excavations at the Syrian coastal city of Ugarit (Ras Shamra) indicate that there was trade in both primary agricultural goods (including grains such as wheat and barley; fruits such as olives, dates, and figs; and honey and spices) and in processed agricultural products (such as olive oil, wine, and cheese) and livestock (including cattle, horses,

sheep, goats, mules and donkeys, and birds). Raw materials for textiles (such as flax and wool), metals (including gold, silver, tin, copper, bronze, and iron), stone artifacts (as found in semi-precious beads made of carnelian), and wood (including cedar, juniper, and cypress) were also traded. Manufactured goods, including metal vessels, wood furniture, baskets, garments, and ceramic vessels, were also part of the inventory of trade items.

The extraordinary preservation of the shipwrecks provides an excellent picture of the actual contents of the Late Bronze Age vessels that moved from port to port around the eastern Mediterranean and shows that the networks of trade and commerce linked Egypt, the coast of Syria-Palestine, Cyprus, and the Mycenaean Aegean islands. Jewelry pieces of gold and silver that used Egyptian, Canaanite, and Syrian designs were recovered. Tools and weapons, including daggers, swords, spearheads, arrowheads, axes, adzes, sickle blades, chisels, knives, tongs, and awls, were made with Canaanite, Mycenaean, Cypriot, and Egyptian designs. Smelted metals were also a significant part of the cargo and were transported in ingots of copper of Cypriot origin (over 145 at Ulu Burun) and tin to destinations where metalworkers would turn the raw metals into finished bronzes. Faience beads and vessels and glass ingots, possibly of Canaanite origin, were also part of the cargo, as were stone Egyptian scarabs; Mycenaean, Mesopotamian, and Syrian seals; and amber beads from the Baltic region. Canaanite, Cypriot, and Mycenaean pottery vessels were also found at Ulu Burun. Specialized materials such as hippopotamus teeth, elephant tusk, and ostrich eggshells were also recovered, presumably for sale to craftspeople at different locations for making into luxury items in their typical local style.

Excavations at Late Bronze Age sites in the Levant have also revealed ample evidence for long-distance trade, particularly in beautiful examples of ceramic vessels of Mycenaean and Cypriot manufacture that, if buried in tomb contexts, are often unbroken whole vessels and perfect examples of their types.

Although trade was a dominant feature of the economies of the Late Bronze Age, in the period between about 1250 BCE and 1150 BCE the

eastern Mediterranean trade collapsed. Among the first indications of the collapse were a series of destructions and rebuildings in the Aegean region. The famous sites of Troy and Mycenae both show evidence of more than one destruction in the final years of the era before a final destruction, above which only locally made ceramics are present. The pattern is similar in Cyprus and along the Levantine coast. The Late Bronze Age ends with often more than one destruction layer, which is then followed in some places by rebuilding with a new and smaller settlement often with a different layout than in previous levels. These smaller-scale settlements lack the traded goods that typified the Late Bronze Age, and the ceramics are all produced from local clays.

A consideration for archaeologists has been whether the evidence for these long-distance trade networks indicates centralized city-state control and management or if it suggests instead that there was a class of independent traders and shippers who operated outside of state control. If the traders were independents, they may have been the Sea Peoples described in the Egyptian texts who were involved in conflicts around the eastern Mediterranean as their trading networks collapsed or were disrupted at the end of the era.

A significant issue is why the Mediterranean trade collapsed. The oldest suggestion is that invaders from southern Europe pushed southward into the Mycenaean region in the Aegean seeking new lands to conquer, and as they conquered the Mycenaeans and destroyed their cities, the trade networks upon which the Mycenaeans depended and to which they contributed were disrupted and collapsed. One set of traders could no longer trade goods with other sets that could then no longer trade for new commodities elsewhere in their trading rounds.

A more recent suggestion is that a key commodity in the metal trade, tin, ceased being available for trade when Anatolian tin mines were exhausted. Once this key commodity was no longer available for trade, the network of trading relationships unraveled because traders could no longer make exchanges for the key commodity needed to manufacture bronze. The lack of tin not only brought the Bronze Age to an end but also encouraged metalworkers to shift focus

and to improve their procedures for working with a more widely available metal—iron.

Newer thinking, however, is that the end of Late Bronze Age trade came about as a mercantile class of traders eventually gained independence from the powerful city-states and empires of the Late Bronze Age and gradually reorganized without the centralized administrative authority of a palace and temple economy that controlled access to, production of, and trade in primary commodities such as grains and metals in addition to manufactured items such as jewelry and pottery. What developed was a decentralized array of smaller cities and small kingdoms that, for a time, depended on local subsistence economies and independent local production of nearly everything people needed to live.

Urban Abandonment

When the Late Bronze Age drew to a close with destructions at many of the major cities of that era, many centers were either abandoned completely or were occupied by a much smaller and poorer population. Examples of cities that suffered such a fate include the famous site of Troy in western Anatolia, Mycenae in southern Greece, Khattusha in central Anatolia, and Ugarit (Ras Shamra) on the coast of Syria.

The famous city of Troy, first excavated by Heinrich Schliemann, suffered a number of different destructions as the Late Bronze Age came to an end. A major destruction in the mid-thirteenth century was followed by a rebuilding before fire again destroyed the central city citadel at the end of the Late Bronze Age. Immediately following the destruction was a poor re-

settlement, which was then followed by another settlement that included handmade ceramics typical of earlier southern European groups. Troy, however, did not regain the magnificence it had enjoyed during the Late Bronze Age.

Mycenae is another famous city that experienced a similar pattern. Approximately a century before the end of the Late Bronze Age, the city suffered some destruction on the perimeter of its massively fortified citadel. This was followed by reconstruction, expansion, and strengthening of the city before it too suffered a serious conflagration. Some parts of the city were never reconstructed before the city was completely destroyed and then abandoned.

Khattusha, the massive and well-constructed capital of the Hittite empire with a strong citadel fortress and huge storerooms, was completely destroyed at the end of the Late Bronze Age in about 1180 BCE and was never rebuilt.

Ugarit was a major city-state throughout most of the Late Bronze Age with a centralized palace and temple economy. Around 1200 BCE the city suffered a massive destruction. Excavation has revealed collapsed walls, burnt plaster and mud bricks, burnt beams, and a random scatter of arrowheads, evidence of the fighting and final defeat of the city. In the level immediately above the destruction and hence dating to years just after, the remains are few and poorer. There was no systematic reconstruction.

The overall pattern at these and other sites suggests a number of possibilities. First is that all over the eastern Mediterranean basin invaders swept through the region systematically attacking and, in many cases, repeatedly attacking major city-states until the urban centers succumbed and finally fell before the invaders swept on to new conquests. However, this assumes that there was a united attacking force with enough power and organization to systematically defeat major city-states in spite of their massive defensive fortifications. There is no evidence to suggest that this was the case. Also, there is no evidence for such a force or for their eventual settlement anywhere in the region.

A more plausible interpretation is that when the centralized palace and temple economies and trade networks connecting the major Late Bronze

Age city-states collapsed, there were relatively minor movements of some groups associated with trade (the Sea Peoples). But the majority of the local population continued to live in the vicinity of the former palatial city-states although now in much simpler and poorer settlements that depended on a subsistence economy. The people lived in what were formerly the hinterlands of the major city-state palace and temple complexes, which were now relatively self-sufficient and able to produce locally all of the food and goods they needed.

The Sea Peoples and Their Destructions

The Sea Peoples were a variety of named groups who appear mainly in Egyptian texts that describe skirmishes and battles during the rules of a number of pharaohs, especially Merneptah and Ramses III, who reigned in the years around the end of the Late Bronze Age. Some of these texts say explicitly that some of these "Peoples of the Sea" had conspired in their islands against Egypt and other Late Bronze Age empires. A common interpretation has been that these Sea Peoples caused the destructions at many Late Bronze Age cities.

Many significant cities in the Aegean region suffered one or two destructions before succumbing to a final defeat preceding complete abandonment. Although sites such as Troy and Mycenae were resettled on a much smaller scale by people whose ceramic traditions derived from southern Europe, the argument has been that Sea Peoples were involved in at least some of the destruc-

tions, either as people displaced by the conflict or as attackers themselves.

The Egyptian inscription of the eighth year of Ramses III details that the invading Sea Peoples conspired in their islands and that no nation could stand before them, including Hatti, Kode, Carchemish, Arzawa, and Alashiya. Hatti, the Hittite empire, crumbled, and its major city Khattusha was indeed destroyed and abandoned at the end of the Late Bronze Age. Although the Hittites were based well inland in Asia Minor, the suggestion has been that an overland wave of Sea Peoples may have caused the Hittite and other inland destructions.

At Cyprus, Alashiya in the Egyptian texts, the Late Bronze Age also ended with destruction or abandonment at many sites, many of which were associated with copper mining, and were also reoccupied during the Iron Age. Ugarit, the site of Ras Shamra on the Syrian coast, suffered complete destruction and abandonment. Copies of diplomatic correspondence between Alashiya and Ugarit indicate that seaborne raiders, likely some Sea People groups, were involved in these destructions.

Along the Syro-Palestinian coast many excavated sites have revealed a clear pattern of destruction at the end of the Late Bronze Age followed by resettlement on a smaller and poorer scale in the Early Iron Age. Sites such as Gezer, Bet-Shemesh, Ashdod, and Ekron all suffered destruction at the end of the Late Bronze Age. In the rebuilding that followed the Bronze Age destructions, there were no imported Aegean vessels, and what pottery that is made in Aegean style is made with local clays. The destructions of these sites have traditionally been associated with conquering Sea Peoples, who then occupied the area. Potters who were very familiar with Mycenaean styles continued to manufacture vessels in the style they knew but used local clays.

Although the widespread destructions marking the end of the Late Bronze Age all around the eastern Mediterranean have been attributed to marauding Sea Peoples largely because of the Egyptian texts, it is more probable that the destructions and the movements of groups of people were associated with a general economic shift from a centralized palace- and temple-

controlled economy to decentralized independent localized subsistence economies. The shift generated unrest and turmoil, which resulted in some conflict and the dislocation of some groups of people. The Sea Peoples and the destructions traditionally associated with them are thus a manifestation of a general and widespread breakdown in the socioeconomic system of the Late Bronze Age.

Thought and Religion

According to Indian legend, the giant serpent (or dragon) Vritra stole all of the earth's water supply, leaving a horrible drought. Vritra hid within his 99 fortresses, hoarding the water for himself as the rest of the earth's inhabitants suffered. A hero arose in the god Indra. This deity, who in some Indian traditions appears to be the lord of all gods, gained the necessary strength to defeat the serpent by ingesting copious amounts of soma, an ancient intoxicant. Indra subsequently destroyed Vritra's fortresses, finally reaching Vritra himself. In a mighty battle, Indra slew Vritra with his thunderbolt, releasing the stolen water and bringing the rivers back to the earth. This and other early stories of the fair-skinned god Indra appear in the Rig-Veda, which was composed orally in India sometime between 1400 and 1200 BCE. The name "Indra" is also found in earlier Mitannian texts, suggesting that this deity may also have been worshipped in Anatolia, which may also explain some of the similarities between legends about him and legends about other Near Eastern deities.

Without the Rig-Veda, modern scholars would know very little about Vedic religion in this period. Thought and religion are two of the most difficult aspects of ancient life for archaeologists to analyze. Archaeologists often recover the material remains of ancient religious practices, such as temple ruins and long-lost statues or figurines. Yet reconstructing religion and thought based on the objects that are left behind can be exceedingly difficult. Thus, for many of the societies that flourished between 4000 and 1000 BCE, only minimal statements can be made about religion with any degree of certainty. This is truly problematic, for thought and religion are key to how people understand themselves and the world around them. Without this information, our knowledge of a society's history is incomplete.

Writing, one of the great innovations of this period, makes a world of difference for the study of religion. Simply put, there is significant evidence regarding the religion and thought of those societies that did utilize writing (at least writing that can be translated by modern scholars). These include Egypt, Mesopotamia, Syria-Palestine, Anatolia, the eastern Mediterranean, China, and India during the Vedic period. Without a doubt, much is lost in translation regarding the thoughts and beliefs of these ancients. Regardless, scholars are on much safer ground discussing the religion of the Egyptians than that of the Europeans, who built Stonehenge.

While there was a diversity of belief and religious practice throughout the world in this particular era, there were general similarities that are worth bearing in mind. Religion certainly does not seem to have been a separate conceptual category for the ancients, and often there is

no word that can be translated in this manner. The ancients did not see religion as a sphere of life that was separate from other aspects of their lives. However, religious work was a job like any other. Temple workers (often translated as “priests,” although this terminology carries connotations of more modern religious faiths) were responsible for mediating relationships between the people and the gods. Temples were not spaces that were open to the public, as churches, synagogues, and mosques are today. Rather, they were places where priests did their specialized work. Most of this work revolved around sacrifice, a formal type of gift

Temples were not spaces that were open to the public, as churches, synagogues, and mosques are today. Rather, they were places where priests did their specialized work.

giving in which something (often an animal, liquid libation, or burnt offering) was presented to the deity in exchange for the deity’s favor in this world. The precise nature of these offerings varied from place to place, but the underlying principle was relatively similar in many regions during this time.

Complicating the study of thought and religion for this era is the fact that this period is particularly important to many present-day faith communities. For Jews, Christians, and Muslims, this was the period in which many of the events of the Hebrew Bible (Old Testament) were purported to have taken place. Even more complex are the similarities and differences between the Hebrew Bible and the contemporary literature and religious beliefs of Mesopotamia, Egypt, and the rest of the Near East. Similarly, some of the most important texts of the Hindu faith were first written down in the Vedas. Moreover, present-day neopagans and other New Age groups view Stonehenge and other monuments from ancient Europe as part of their own religious heritage, even though there are no direct historical connections with the ancient traditions, and their practices and beliefs today vary considerably from those of the ancient Europeans. Even the Greeks and Romans drew inspiration from this period, believing that the *Iliad* and the *Odyssey* referred to events that occurred in this period. Moreover, classical Chinese texts regarding the Mandate of Heaven and other core ethical concepts purport to date to this era. That many modern beliefs have their origin in this period is unquestioned, but understanding the precise relationship between modern and ancient beliefs can be very difficult. An important caution to keep in mind as a historian is to be aware of the subtle anachronisms that are imposed upon ancient religious texts by members of modern faith communities, who often read contemporary values and beliefs into texts that were written long ago.

As this is the period in which writing was first invented, it provides the earliest evidence for what could be understood as philosophical explorations. Vedic texts suggest what constitutes a proper approach to leading one’s life: the repayment of debts that all individuals owe to the gods, the primordial sages, the ancestors, and to fellow humans. Near Eastern explorations of what constitutes the good life can be found in wisdom literature, a genre of writing that is attested in Egypt, Mesopotamia, and the Hebrew Bible. Usually, wisdom literature takes the form of collections of pithy sayings, passed on from a teacher or elder to a

student. Issues such as how to conduct oneself in different settings, questions of personal morality, and what constitutes success are all dealt with—although not uniformly—across this tradition. Other Near Eastern texts discuss why bad things happen to good people, why suicide is not appropriate, and why things change, all questions that are still being asked in our current era.

■ Introduction: Creation Myths and Cosmology

Many of the traditions about the nature of the universe, its origins and its composition, which are held by religious communities in the present day are derived from observations and understandings that arose in the period from 4000 BCE to 1000 BCE as humans began asking: Where did we come from? How was the world created? What does the universe look like and how does it operate? How do celestial bodies relate to our planet? These are all questions that people asked about their world in this distant past that we are still asking today.

What follows is a discussion of some of the major creation myths and cosmological accounts that date from this early period. Some show remarkable similarities to those held by faith communities today. Some seem completely alien to the present scientific worldview. Attempting to understand how ancient people understood these stories can be very difficult. Often there was more than one creation story circulating at a given time. How did they harmonize the differing accounts or did they even try? How literally did they take these accounts? Did ancient people really believe that the mythological events that transpired to create the universe actually occurred? Or, did they treat these myths as a means of expressing the inexpressible in language that would make sense within their own experiential framework? These viewpoints are heavily debated by scholars. No answer is provided here, but it is important to be aware of this debate when exploring these ancient conceptions of the universe.

Keep in mind that these stories were not just neutral scientific accounts. Many of these an-

cient creation stories and cosmological accounts were intended to explain the lived reality of the ancient world and to justify its institutions and social structure. Lurking beneath many of these stories are justifications for situations that were politically loaded at the time in which the stories were composed (for example, different creation accounts from ancient Egypt justify the location of different political capitals). There is more than one argument in many of these tales. They are not just accounts of how the world was created but are accounts of how the world should operate (from the perspective of the ancient writer).

—Kevin M. McGeough

Egyptian Creation Myths

The creation and continual maintenance of an ordered world from primordial chaos was the foundation upon which virtually all ancient Egyptian myth and ritual rested. Because divine creation, or cosmogony, was beyond the scope of human perception, Egyptian theologians developed a number of different creation myths to account for its processes. Each of these myths approached the question of the world's origin from a different perspective or sought to clarify some aspect of its genesis to which other accounts may only have alluded. It is important to note, however, that the various creation myths do not appear to have been conceived as competing theories. No two cosmogonies were mutually exclusive, even when their explanations involved different physical or magical mechanisms or emphasis upon different groups of divinities. This

THE EGYPTIAN WORLDVIEW

The ancient Egyptians, like many societies, conceived of their land as a sort of *axis mundi*, literally the “center of the world.” The view was based in large part on the geographical isolation of the Nile River valley from the surrounding lands. The river provided a self-contained system that rarely required venturing beyond its naturally defined borders except for acquiring certain foreign commodities, such as Lebanese cedar or Nubian gold. To the ancient Egyptian, the sun rose and fell on Egypt itself, which was felt to represent a bubble of light and order in a sea of chaos. Neighboring countries and their people were, by default, thought to reside outside this ordered realm; many state and private texts attest to the common practice of ritually destroying the names of foreigners as a means of magically holding these chaotic powers at bay. The belief of the centrality and, by extension, superiority of Egypt and its people was even reflected in the language: the word for “people,” *remetch*, was used for Egyptians alone, while those who lived beyond its borders were relegated to the lesser status of *khastiu* (“hill-dwellers”), that is, foreigners.

—Joshua Roberson

multiplicity of approaches instead exploited the flexibility of metaphor and symbol as tools for the expression of concepts that were essentially inexpressible.

Our understanding of Egyptian creation myths is shaped to a large degree by scattered allusions found in royal and private mortuary literature, specifically the so-called Pyramid Texts, Coffin Texts, and Book of the Dead. Additional material may also be extrapolated from oblique references found in hymns to the gods, magical texts, and certain cosmological treatises. However, no comprehensive account of creation is known from any one composition. This may simply be due to the nature of the preserved sources, which were concerned primarily with practical matters such as the protection of the deceased, ritual activity, royal legitimation, etc. Such texts tend to allude to cosmogonic episodes for the purpose of establishing a mythological precedent to some desired outcome. In such cases,

The god Atum, from the Tomb of Nefertari, Valley of the Queens, Thebes (Corel)

therefore, the creation story functions as a means to an end rather than an end in itself.

The so-called Heliopolitan Cosmogony is of central importance for any understanding of the broader concepts relating to creation in ancient Egypt. This mythological tradition derives its modern designation from the city of Heliopolis, known to the Egyptians as Iunu (biblical On), which was the principal cult center for the sun god Re. However, it must be stressed that despite a degree of solar emphasis, this cycle of myths existed independently of Heliopolis or any other city.

In this tradition, the cosmos necessarily begins with the creator god Atum, whose name at once connotes completion, finishing, and not-being as befits a demiurge whose existence precedes creation itself. In addition, Atum is also associated with the setting sun, and his name is frequently compounded with that of the sun itself, as Re-Atum, in the Pyramid and Coffin Texts.

This syncretism serves to reinforce the identification of the creator with his most important manifestation, the sun.

Initially, Atum merely floats, motionless and inert, within the infinite primordial ocean of Nun. This primeval state is frequently described in negative terms as the antithesis of the ordered cosmos: nothing yet exists, neither gods nor light nor time nor space. In a parallel tradition, Nun was quantified by four additional characteristics: boundlessness or flood (*hebu*), water (*nu*), darkness (*keku*), and chaos (*tenemu*). Atum rests within this watery expanse until the creative potential inherent within him—described as *heka*, or magic—results in his awakening and the subsequent emergence of the first mound of earth from out of the waters, the birth of the sun, and initiation of the natural order of the cosmos.

Following this initial act of creation, Atum then begets the first pair of deities, Shu and Tefnut, representing the principles of air or dryness and moisture, respectively. The problem of parthenogenesis—reproduction without sexual union—was circumvented by the Egyptian theologians, who describe the emergence of Shu and Tefnut from Atum's body as the result of an act of masturbation. An alternate explanation relies upon wordplay to describe how Atum sneezed (*ishesh*) Shu and spat (*tef*) Tefnut. The creation of these two deities, one male and one female, introduces the possibility for true procreation, and their resulting union produces an additional male and female pair: Geb (the Earth) and Nut (the Sky). These two gods in turn beget four additional sons and daughters: Osiris, Isis, Seth, and Nephthys. This original Ennead, or group of nine deities, implies the sum of all gods, that is, the totality of creation, given the particular status of the number nine as a superlative plural, or a nonspecific indicator of many deities.

The development of the Ennead represents only one facet of the basic framework upon which Egyptian religion was predicated. The institute of kingship, as personified by Horus, the son and legitimate heir of Osiris and Isis, also forms a critical component of this mythology, linking the political necessity of the state with the environmental reality of the Egyptian cosmos. In addition, the pivotal role of the sun for

both the living and the dead as well as the maintenance of cosmic order, or *ma'at*, cannot be overemphasized. Parallel to the Heliopolitan cosmogony were a number of additional traditions, which both complimented and expanded upon its themes. The theologians of Hermopolis eventually developed the four characteristics of the primordial ocean into an Ogdoad of eight deities, who were seen as the actualizing principle that enabled the development of Atum himself. Other myths expanded upon cosmogonic themes such as the sun's emergence above the primordial mound, described variously as the flight of the *benu* heron (the archetype for the Greek phoenix) or the emergence of the child-god Nefertem from the first lotus blossom. A later tradition cast the chief deity of Memphis, Ptah, in the role of the primordial creator who develops the cosmos through the power of creative speech. This characteristic of the Memphite theology may thus be compared with the Greek *logos*, which finds its most well-known expression in the biblical conception of the Word.

Near Eastern Myths of a Deluge

While stories of a universal deluge, or flood, appear in many cultures, those from the ancient

► THE FLOOD STORY IN THE GILGAMESH EPIC

The Gilgamesh Epic, a masterpiece of Akkadian literature, narrates the adventures of Gilgamesh and his foe-turned-friend Enkidu and the former's search for eternal life. Gilgamesh was an Early Dynastic king of Uruk around whom a number of legends (in Sumerian) eventually gathered, forming the earliest sources for the later Standard Babylonian version of the epic discovered in the library of the Assyrian king Assurbanipal. More than 200 fragments of the story have been discovered in various parts of the Near East, as far as Hattusha (present-day Bogazkoy) in Anatolia and Megiddo in the Levant, and attest to its importance in ancient Near Eastern culture and thought.

—Joseph Lam

Near East are the earliest attested and are therefore of primary interest for investigating the origins of this motif. Some striking similarities between the biblical and Mesopotamian accounts in particular point to a common literary tradition for these stories.

The biblical account of Noah in Genesis 6–9 is undoubtedly the most famous of the ancient Near Eastern flood stories. It tells of how, when wickedness on the earth had increased greatly, God became so grieved that he decided to wipe out all creatures on the earth. However, he chose Noah, righteous among his generation, to build an ark into which he would bring his family as well as specimens of every animal. When God sent the flood, all life on earth was destroyed, but those in the ark rode above the waters and were spared. Afterward, God made a covenant with Noah to never again destroy all life with a flood.

Ancient Mesopotamia retained a number of traditions concerning a universal deluge. This is not surprising given the susceptibility of the area to seasonal flooding. Three major stories of a deluge have been preserved. The Standard Babylonian (Akkadian) version of the Gilgamesh Epic contains an episode in which Gilgamesh approaches Utnapishti to inquire about eternal life. In response, Utnapishti recounts how long ago the great gods decided to send a destructive del-

uge. The god Ea, however, revealed the matter to Utnapishti, commanding him to build a boat. When the flood came and those in the boat survived, the god Enlil became angry that their plan had been thwarted. In the end, it was decided that Utnapishti should be allowed to live but in a faraway land. Although no reason is given for why the gods sent the deluge, parts of the story hint at population control as the underlying motivation.

The theme of population control is more explicit in the earlier Akkadian epic of Atrahasis. In this story, the gods created humanity to alleviate their burdens, only to become annoyed by the excessive noise they made. The result was a number of attempts at decimating humanity: plague, drought, famine, and finally a flood. As in the Gilgamesh account, the hero Atrahasis is told of the plan and survives in a boat.

The hero of the Sumerian flood story (also called the Eridu Genesis) is Ziusudra, who is also the last antediluvian king named in the Sumerian King List. While this text contains a number of gaps in key places, enough has been preserved to show its structure as a kind of primeval history. Xisuthros, the hero in the third-century BCE flood account of Berossus, is clearly a Greek rendering of the name Ziusudra.

Two Egyptian tales are worth mentioning. The Destruction of Mankind tells of the destruction of a large portion of humanity in a beer-based liquid resembling blood, while chapter 175 of the Book of the Dead hints at a future devolution of the earth into an original floodlike state.

Mesopotamian Creation Myths

Copies of various Mesopotamian creation accounts, or cosmogonies, written in the cuneiform language on clay tablets have been found throughout the entire Middle East. For the an-

cient Mesopotamians, such cosmogonies were not designed to explain scientific or even historical information but instead were intended to convey information about the contemporary reality of the world through theologically diverse traditions of the myths of the gods.

The sources that contributed to the Mesopotamian study of creation include third- and second-millennium cosmogonies written in the Sumerian language (god lists, narrative texts from both the cities of Nippur and Eridu, and some unique minor texts) as well as midsecond- and first-millennium cosmogonies written in the Akkadian language (anthological cosmogonies such as *Atrahasis* and *Enuma Elish* and minor cosmogonies). Despite the numerous differences in the details and languages of all of these sources, the goal of these creation stories was to give the cosmos order, function, and purpose. All of the traditions emphasized the divine assignment of destiny (Sumerian *namtar*) whose origins were defined by the gods in the plan of the universe. Since the order of the cosmos was perpetually threatened in the ancient Near East, the king and his people limited the spread of chaos through yearly rituals, rites, and festivals.

From the Nippur tradition and the early god lists, scholars can reconstruct the primeval birth of civilization from the parental gods of Mesopotamia. In that day, creation culminated in the single act of the union of heaven (AN) and earth (KI). Vitality, organization, civilization, and social order ensued from this cosmic marriage, but their union was short-lived and separated by the first offspring of the gods, Enlil. From the narrative texts of the Eridu tradition there is a different account whereby creation ensued from the god Enki, the personification of underground spring water, who watered the earth (fertility) and created mankind from human clay (wisdom culture). Water was the source of beauty, being, and form in the Eridu tradition, and so this stream of tradition in Mesopotamia was heavily dependent on the principle of life being from underground, or chthonic and not cosmic sources, as was the case in the Nippur tradition.

Although many of the diverse themes found in the Sumerian cosmogonies listed above are discovered in the Akkadian cosmogonies (e.g., formation of mankind, the decree of destiny, the

Tablet telling the Epic of Creation, from Nineveh, northern Iraq, Neo-Assyrian, seventh century BCE. This particular tablet relates the episode in which the god Anshar summons the gods to celebrate Marduk's appointment as champion following his defeat of Tiamat. (The Trustees of The British Museum/Art Resource, NY)

➤ NEW YEARS' CELEBRATIONS

The New Year's Festival was originally an agricultural springtime ceremony whereby the Mesopotamians gathered to renew the fertility of their land through a series of elaborate rituals. The ceremony evolved into an annual celebration at Babylon for 12 days in the first month of the year, the month of Nissanu (our March 20 or 21), where the rites focused on the cult of the Babylonian god Marduk. In this most elaborate and important Babylonian ritualistic festival, preserved in fragmentary cuneiform tablets from circa 1000–600 BCE and the Hellenistic period, the destiny of the kings as well as the people was decreed and fixed for the year. After the performance of a series of private rituals, including the recitation of prayers by the high priest and the construction of wooden statues as divine images, the high priest would stand before the people and recite the Babylonian Epic of Creation, *Enuma Elish*. The reading was followed by a ritualistic performance of the humiliation of the king whereby the high priest would slap him on the face, force him to kneel before the statue of the god, and strip him of his divine authority. Afterward, the king would utter a negative confession (“I have not . . .”) and thereby reaffirm his humble place in the cosmos. Then, the statues of the gods and goddesses from nearby cities would arrive in Babylon to honor the god Marduk and his supreme place in the pantheon. In the final days of the festival, the king would lead the statue of Marduk by the hand from the temple to the shrine of the destinies, where the fate of the king, his land, and his people would be divinely decreed by the god for the new year. Once the cosmos and land were restored, a processional led participants to a grand banquet, which lasted for three days. The gods and the people would finally return to their cities, assured by the fixing of creation, and would wait to assemble again the next year.

—William Zimmerle

temple as the original place of creation), the Akkadian cosmogonies of the second millennium later discontinued the idea of a cosmic marriage between the heaven and earth and emphasized blood instead of water in the creation of mankind. These later anthological cosmogonies were

complex literary works that probed the divine-human relationship, the limits of mortality, and the dignity of humanity. *Enuma Elish*, for example, the Babylonian creation epic in its completed form of seven tablets, was a political tract that traced the kingship of Marduk to the foundation of the cosmos before any divine authority existed. Its ultimate purpose was defined in its end with the exaltation of Marduk as the most powerful and supreme head of the Mesopotamian pantheon. And in the epic of Atrahasis, humankind, which was first created to serve the gods from the flesh and blood of an Igigi god, overpopulated the earth so much so that the gods, their original creators, set out to destroy them by means of plagues and a flood. Like the biblical story of Noah in Genesis 6, the god Enki instructed Atrahasis and his family to build an ark to survive the flood. In the end, humankind was saved because the Mesopotamian gods realized their own selfish need for humanity and thus repopulated the earth. But new safeguards were designed and implemented, and there were now limits on the mortality and reproduction of humanity set within in the cosmos.

The underlying cosmological realities of the ancient Mesopotamians that were designed to express the universality of the present state of their world are evident in the overall construction of the various cosmologies discussed above, from the minor cosmogonies to the major anthological ones. More broadly stated, these realities include three aspects of function found in the literary structure of the myths: naming, splitting, and role assigning. First, the giving of names was seen as an important way in which creation was accomplished. In the beginning of the Mesopotamian creation myth *Enuma Elish*, for example, the heavens, earth, and the gods were nameless. When the gods Lahmu and Lahamu were born, their names were pronounced. The idea of destroying or splitting the divine was a second functional aspect of creation. Marduk, the divine Babylonian hero in *Enuma Elish*, cut the goddess Tiamat in two, for example, whereby he created the cosmic geography of the universe. But the primary functional aspect of all these myths was the assigning of destinies decreed to both humanity and the gods, an idea

attested in *Enuma Elish* whereby Marduk re-formats the cosmos so that everyone and everything has its place.

Vedic Creation Myths

An early myth emerges in fragments from the first and tenth books of hymns in the Rig-Veda. In the myth are the familiar themes of the sacrificial basis of creation, incest, and the separation of the first “parents” who, although of opposite gender, resemble the traditional depiction of the Egyptian Nut (heaven) arched over Geb (earth). We are also reminded of the Greek story of the merging of heaven and earth as Uranos and Gaia.

The phallus of Heaven, the male force, reached out to the young girl, his daughter, Earth. Agni, the god of fire, had made the hot passion and seed of Heaven. As the act of union was committed, some seed spilled onto Earth, and words and the rituals were born. The god had satisfied himself with his own daughter. Out of the hot spilled seed came the Angirases, the mediators between gods and humans, who distribute the gifts of the gods. Heaven is our father, and Earth is our mother.

Another Rig-Veda myth, also from the tenth book, emphasizes the traditional creation myth theme, the sacrifice of a being out of whose dismemberment the world is made. The 1,000-

headed, 1,000-footed primal man, Purusa, enveloped earth and was, in fact, the universe, the here and the there, the now and the always. Three-quarters of Purusa are of the undifferentiated immortal sphere, while one-quarter is the sphere of life's forms.

When the gods performed the sacrifice of the primal man, his bottom quarter became the world we know. His mouth, out of which came words, became the wise brahmin priest and the god Indra. His arms became the warrior caste, his thighs the common people, and his feet the lowest of the low. Out of the sacrifice of Purusa came the beasts, plants, rituals, and sacred words and the Vedas themselves. From Purusa's mind came the moon, from his eye the sun, from his breath the wind, from his head the sky, from his feet the earth, and from his navel the atmosphere.

By sacrificing Purusa, the gods sacrificed he who gave of himself. In so doing they made sacrifice to sacrifice and gave birth to the foundation of our order.

In the tenth book of the Rig-Veda there is still another hymn of creation. It speaks of the necessity of opposites. Without Non-Being there cannot be Being; without Being there cannot be Non-Being. It is a human cry for knowledge of origins, for the meaning of Self, the meaning of Being. The poet asks, “Who knows the source of this creation?” If in the beginning there was neither Being nor Non-Being, neither air nor sky, what was there? Who or what oversaw it? What was it when there was no darkness, light, life, or death? We can only say that there was the One, that which breathed of itself deep in the void, that which was heat and became desire and the germ of spirit.

The wise say that Non-Being and Being became one and that chaos became order. Who really knows what happened, whether it came from the One or not? Only the creator knows, and maybe even he knows nothing about it.

Chinese Creation Myths and Cosmogony

Cosmogony concerns theories of the origins of the cosmos. Creation myths communicate traditional versions of these theories. Some creation myths illustrate striking cross-cultural similarities, while others demonstrate variation between cultures or even within a culture. Over time, a number of Chinese myths have addressed the creation or repair of the cosmos, humans, and the Chinese landscape. Mythic themes, such as a great flood or the cosmogonic separation of heaven and earth, are common cross-culturally. However, in the Chinese myths, the flood story concerns righteous rulers and cultural heroes creating a more orderly and inhabitable world rather than divine punishment or the need to create the cosmos or its inhabitants anew. Despite China's long literary tradition, its mythology is fragmentary with relatively little emphasis on creation myths. Moreover, Derk Bodde and twentieth-century Chinese scholars have demonstrated a surprisingly common inverse relationship between the supposed age of a myth and its actual appearance in Chinese literature. That is, creation myths and similar legendary accounts of the very earliest times appear to be later literary contributions rather than myths, songs, and documents addressing less ancient legendary and historical figures.

There are various related reasons that might explain why creation myths have not been as central to Chinese mythology and why the myths we have are fragmentary and often deliberately altered rather than transmitted whole. It is particularly difficult to access myths from Shang and earlier periods, although Sarah Allan has attempted to reconstruct a Shang origin myth that maintained that they were born from one or more eggs that came from blackbirds, who were the ten suns, that are linked to Shang divine ancestors and may be the basis for the Shang ten-day calendar. Elements of this reconstruction appear in various sources and times

and connect with other myths, such as a well-known legend in which nine of the ten suns were shot down by an archer to save the earth from their heat when they mistakenly all came out at once. This reconstruction is speculative due to the fragmentary nature of the sources and the distortion of some early myths by later scholars who disregarded some elements as irrational and transmitted portions of myths that served their purposes.

Confucian scholars have been important transmitters of tradition; however, their interests shaped this transmission by historicizing myths. Legendary figures were recast as more human rulers, heroes, or villains. Their activities were placed in a time line, and they were used as model sages to emulate or as delinquent foils and counterexamples whose negligence led to disasters. The Confucian scholars were not unusual in appropriating myth to support their worldview. Schools of Chinese philosophy in general often employed legendary accounts to exemplify the presence or absence of order and harmony in social relationships, in the natural world, and in an integrated cosmos constantly changing according to interrelated and predictable phases, patterns, and correspondences between heaven and earth, deities and humans, ancestors and living relatives, human bodies and political bodies, social organization and divine governance, and additional pairings and developments in nature, society, and history.

This worldview of correspondences and phases arises from and continues to shape the long and rich Chinese history of literature and thought devoted to cosmology. Cosmology includes cosmogony's concerns with the origins of the universe, but it encompasses a broader study of the nature and ongoing development of the cosmos aimed at understanding its order and patterns and the position, nature, and role of human beings. Cosmogony and creation myths have played a relatively limited and subordinate role within the larger concerns of cosmology. Moreover, the fragmentary and relatively late appearance of the best-known creation myths raises questions of their age, the regional origins within or beyond China, and the direction of influence between these creation myths and cosmological assumptions in China.

➤ CREATION MYTH OF PANGU (P'AN-KU)

The Chinese cosmogonic myth of Pangu tells the story of the separation of heaven and earth and the creation of the cosmos. Derk Bodde paraphrases this myth and indicates that although the myth's subject encompasses the earliest primordial origins of the cosmos, we only know of this account from references to a now lost third-century CE source, which is far from ancient by Chinese standards. This myth does invoke the considerably more ancient idea of an original undifferentiated whole (*hundun/hun-tun*), which like an egg gave birth to Pangu and then 18,000 years later split into heaven above, with corresponding yang connotations, earth below, with corresponding yin connotations, and the still-growing Pangu in between. Pangu's growth over the next 18,000 years further separated heaven and earth, which were also expanding. Just as Pangu's life is inextricably bound to the differentiation and separation of heaven and earth, yang and yin, his death produces the cosmos as we know it. Pangu becomes a cosmogonic organ donor whose "breath became the wind and clouds, his voice the thunder, his left and right eyes the sun and moon respectively, his four limbs and five 'bodies'

(fingers?) the four quarters of the earth and the five great mountains, his blood the rivers, his muscles and veins the strata of the earth, his flesh the soil, his hair and beard the constellations, his skin and body-hair the plants and trees, his teeth and bones the metals and stones, his marrow gold and precious stones, and his sweat the rain. The parasites of his body, impregnated by the wind, became human beings" (Bodde). This creation myth includes themes and images found elsewhere in Chinese literature and beyond China. Creation from the dismemberment of a giant being is similar to the sacrifice of the cosmic man, Purusha, found in earlier Vedic literature. Moreover, the origin of the sun and moon in Pangu's myth recur in the later Japanese creation myths where Izanagi gives birth to the sun and moon from his left and right eyes respectively.

Source

Derk Bodde, "Myths of Ancient China," in *Essays on Chinese Civilization* (Princeton, NJ: Princeton University Press, 1981), 45–84.

There are a number of important myths that convey how legendary culture heroes—such as Yu, Shennong, and the Yellow Emperor—advanced Chinese civilization by carving order out of chaos or inventing technologies to improve agriculture or stimulate cultural progress. References to these myths in the *Shi jing* (*Classic of Songs*) or the *Shu jing* (*Classic of History*) are earlier and more influential than true creation myths. Yu reshapes China in the process of draining the floodwaters, but he does not create it. Nu Gua (Nu-kua, Nüwa), in some legends, creates human beings. She too exists in an already created cosmos, but she is credited with repairing that cosmos and creating humans. The technique by which she creates human beings changes from carefully forming some by hand out of yellow earth to quickly flinging others together by dragging a cord through the mud. This explains and reinforces class distinctions between nobles and common people, respectively.

The legend of Pangu (P'an-ku) is most clearly identifiable as a creation myth. This is a classic tale of cosmogony whereby heaven and earth separate, and humans and the rest of the created world arise from the death of a giant cosmic being. There are additional myths that depict the separation of heaven and earth. Some resonate with myths from around the world in their sense of an earlier time with closer links between heaven and earth, gods and humans. In contrast, later times present greater difficulty communicating between the increasingly separate realms and necessitate a more arduous existence for human beings. In one interesting twist on this theme, there is a Chinese myth that claims that one of the columns separating heaven and earth broke and later became uneven once again despite Nu Gua's cosmic repairs. As a result, heaven and earth slant closer to each other in the northwest and farther away in the southeast. This myth provided explanation for why the heavenly

bodies move to the west while the major rivers in China flow out to the ocean in the east, where water had pooled when the column first broke.

Studying the cosmos and the way the universe is arranged and unfolds becomes important for reasons beyond astronomical or even astrological interests. The latter, in fact, may be a better guide, as there is a strong sense of the predictive power of natural observations due to the premise of shared phases, patterns, and correspondences. Understanding the workings of the cosmos was deemed important to understanding the workings of human beings individually and collectively. To comprehend and help keep in alignment the ways of nature and the ways of society are inseparable from issues of how to lead one's life. Cosmology, in short, has informed the worldview in China on all levels while connecting those same levels and directing the ideal course on one's life and one's role in society and the universe. Cosmogonic stories inform cosmological assumptions, but in the case of Chinese mythology, their relatively late appearance in literature suggests that some of them may have been the product rather than the source of dominant cosmological views.

Cosmological Themes in Chinese Art

In the middle to late Neolithic era of 3,500–7,000 years ago, prehistoric people within the modern

boundaries of China had some complicated ideas related to myths. The patterns and decorations molded or carved on stone, jade, bone, wood, and pottery tell mythical stories. Comparing these relics with ancient writings provides clues about the myths of that time. In Hemudu village in Yuyao County, Zhejiang Province, a bone dagger was found in 1973 that dated back to 7,000 years ago. On the handle of the dagger was a carved pattern depicting two symmetrical birds carrying the sun. This motif of a bird carrying the sun can also be widely found on pottery in many cultural relics from modern Gansu, Shaanxi, Henan, and Shanxi provinces.

Classified as the Miaodigou Type of Yangshao culture (a Neolithic culture of central China), these relics are usually dated to 6,000 years ago. In these relics the bird carrying the sun is sometimes depicted with three legs. This same motif can be found in myths recorded in ancient writings, such as *Shanbaijing* (*The Classic of Mountains and Seas*, ca. fourth century BCE to the early part of second century BCE), *Huainanzi* (ca. 139 BCE), and *Lunheng* (*Critical Essays*, written by Wang Chong, 27–ca. 100 BCE). According to these texts, there was a crow settling on the sun (some versions say there were ten crows settling on ten suns). The crow functions as the spirit of the sun or, variously, the one who carries the sun across the sky. Sometimes the bird is said to be three-legged. According to an account in *Shanbaijing*, there was a huge tree named *Fusang* (Leaning Mulberry) in the eastern Tang Valley. In its branches rested the ten suns. As soon as one sun came back from its journey crossing the sky, another sun started forth. Each of the ten suns was carried by a crow.

An earlier text, "Tianwen" ("Questions of Heaven," written by Qu Yuan, ca. 340–278 BCE), ambiguously mentions the crow of the sun in the story about the mythical hero Yi, asking: "Why did Yi shoot down the suns? Why did the crows shed their feathers?" Wang Yi (ca. second century CE), the commentator of "Tianwen," cited a paragraph from *Huainanzi* to explain these questions, stating that at the time of Yao (a demigod of the three sage kings), the ten suns rose together and burned up the woods and grass. Yao then ordered Yi to shoot down the ten suns in the sky, and Yi shot down nine of them. The

nine crows settling on these suns died, and their feathers fell out. In later versions, the crow of the sun is sometimes said to be three-legged.

Thus, it can be concluded to some degree that in the middle to late Neolithic era, the mythical motif of a bird carrying the sun or a bird settling on the sun (the number may be interpreted as plural) is already quite developed. Those ancient written myths are not just single occurrences of such mythical ideas. Instead, they receive support from artifacts found by archaeologists and it can be deduced that these mythical beliefs were widespread. It may be further assumed that the designs carved on bone or other materials were telling the sun myth in an-

other way, not in spoken language, but in drawings and engravings.

■ Introduction: Ancient Deities

From the period 4000 to 1000 BCE, polytheism was, for the most part, the norm in ancient religions. Polytheism is the worship of more than one deity, usually distinguished from monotheism (the worship of one god, which is characteristic of Judaism, Christianity, and Islam). The collection of gods worshipped in a polytheistic community is usually referred to as a "pantheon," although pantheons were not fixed and unchangeable. Sometimes these deities were seen as anthropomorphic and were thought to have the personalities and physical appearance of humans. Other times, the conceptualizations of these deities was relatively abstract. Often deities were associated with particular aspects of earthly life, but these associations were fluid and varied depending on a number of variables.

Polytheistic practices are quite diverse, and it is difficult to make meaningful generalizations. Usually, members of a polytheistic community do not worship all of the gods or goddesses with equal fervor. Some communities had particular deities within the pantheon that had a special relationship with that region. Sometimes groups of individuals within a community (such as a guild of specialized workers) felt that they had a particular relationship to a deity based on shared interests or the individual characteristics of the deity. Other times families and individuals per-

ceived themselves to have a close connection to one particular deity and emphasized the worship of that particular god or goddess. The veneration of specific deities was sometimes emphasized in special circumstances, such as when a member of the community was sick and deities perceived to have a certain healing skills or influences were invoked.

Polytheistic societies often believed in other supernatural or semidivine forces that they did not consider to be gods. Spirits, demons, ancestors, and other unseen beings were often thought to inhabit the world and play a role in the community's life. Scholars who study religion from a comparative perspective often divide the deities and other supernatural beings of polytheistic societies into a number of categories, although one needs to always be cautious about comparative approaches to religion that can overemphasize cross-cultural similarities. Celestial deities are those deities that are related to heavenly bodies, such as the sun, moon, or stars. Cthonic beings, in contrast, are associated with earth or places in the earth, such as bodies of water or caves. The following entries discuss some of the deities of a number of regions but should by no means be considered exhaustive. Rather, they provide a general sense of the diversity of deities worshipped from 4000 to 1000 BCE.

—Kevin M. McGeough

African Deities

African religious systems of antiquity were associated with several theological concepts and assumptions. By 1000 BCE, African deities had evolved out of a particular ecology and spiritual environment. The universe was believed to be populated by numerous spiritual entities and divinities called *neteru* by Egyptians and Nubians and in a later era *orisas* by some West Africans. It was believed that these divinities were a manifestation of divine intelligence and presided over mountains, hills and valleys, seas, rivers, streams, trees, forests, and shrubs.

They controlled the world and facilitated divine action. Some were more important than others. Spirit possession as well as invocations and libations to the divinities became elaborate over time. Protective amulets were worn by people who acted as spiritual intermediaries such as the *kher-heb* of Nubia and Egypt, the Yoruba *babalawo* of West Africa, and the *sangoma* of South Africa. There was also the belief that dead ancestors returned in various earthly forms. In

some parts of the continent, however, including parts of Nubia and Egypt, the heads and limbs of corpses were sometimes amputated in the belief that this act would prevent their return.

Ethiopia is one of the four major regions of ancient northeast Africa, along with Nubia, Punt, and Egypt. Arwe and Atete are two female deities who played a prominent role in the Ethiopian pre-Judaic and pre-Christian era. According to an Ethiopian sacred narrative, one of the eponymous deities was Arwe, who was the supreme deity of the land, particularly northern Ethiopia. Arwe was believed to be half human and half animal. His father was a *zendo* (serpent), and his mother was human. He presided over many gods and goddesses.

One of the famous female deities of Ethiopia was known as Atete, but Arwe may have been more prevalent prior to the mastery of highland agriculture, particularly crop farming. Legend has it that Arwe was supplied annually with cows, goats, sheep, and milk. The sacrificial offerings were also made up of humans and animals. This suggests that the tradition of Arwe may have been observed by pastoralists.

Atete, a female deity, originated in southwestern Ethiopia at a nonspecified time. The deity is more popular with the Oromos even though there are some Amhara and Gurage followers. She was believed to have supernatural powers and was capable of shaping the destiny of believers. Unpropitiated, Atete may spread misfortune, such as untimely death, poor harvest, poor health, and misery. Atete was considered an intermediary between human beings and the divine. She was regarded as a representative of the gods on earth (and later of the Judeo-Christian God). According to her followers, the criterion for a smooth life was to offer to her annual gifts.

Atete was known by many names: Atete Ginbi, Atete Hara, Atete Dula, Atete Borona, and Atete Gurage. These were regional, activity oriented, and leadership Atetes. In other words, additional designation may be included to highlight specific activities or desires. For instance, Atete Hara is a lake or sea deity and is regarded as kind and forgiving. On the other hand, Atete Duala is a deity of war recognized for toughness. All of these Atetes may be evoked together or simply as Atete depending upon special circumstances.

➤ DIFFICULTIES IN THE STUDY OF AFRICAN TRADITIONAL RELIGIONS

There are a number of difficulties which historians who attempt to study traditional African religions face. The most problematic is the issue of sources. Much of the knowledge about these religious beliefs has been passed down in oral (as opposed to written) form. Over time, these oral traditions have been altered to reflect changing historical circumstances and it can be very difficult to identify the period that different traditions reflect. One of the approaches that scholars have taken is linguistic. Christopher Ehret, for example, has studied the history of the African languages in which these oral traditions are preserved and by looking at linguistic changes, he identified various phases in African religious history. Studying this historical-linguistic evidence in tandem with archaeological evidence helps scholars reconstruct ancient African religion.

—Kevin M. McGeough

Christopher Ehret. *The Civilizations of Africa: A History to 1800*. Charlottesville: University of Virginia Press, 2002.

Atete was symbolized by chains of fine multi-colored beads, or *chale*, which were kept in a straw basket. Atete was celebrated on September 11 or 12, which coincided with the Ethiopian New Year. The ceremony was usually conducted by a woman who took ground barley and spread this over a handful of fresh green grass. The *chale* were taken out of the basket and were held in both palms, wet with fresh butter and perfume. The woman moved these gently over her face and torso before she evoked Atete for good omen. This ceremony evolved over the centuries.

Ta-Seti, Kerma, Napata, and Meroe were some of the major centers of power associated with ancient Nubia. These kingdoms and empires prevailed between 3800 BCE and 200 CE. Auset (Isis), Heru (Horus), Hapi, Ra, Tehuti (Thoth), Amen, Apedemak, and Ausares (Osiris) were some of the various deities worshipped and recognized by the Nubians. Some of the deities are of Egyptian origin, but Dietrich Wildung does not rule out the possibility that basic aspects of Egyptian religion may have originated in Nubia and northern Sudan in the first instance. By 1000 BCE, the Kushite kingdom of Napata was in its early stages, and so too was the religious awe associated with Gebel Barkal, the holy mountain of Napata. Apedemak, the god of war, was represented as a snake with a lion head, and Ausares, the god of immortality and resurrection, was also revered. Numerous temples were built in their honor.

Many of these spiritual entities may be perceived also as energies, agents, gates, angels, spiritual helpers, and conscious thought forms. They represented principles and concepts as well. They were associated with specific head gear and dress, animals, plants food items, gestures, sacred objects, symbols, chapels, temples, and also pyramids, about 200 of which were constructed within the millennium in the case of Napata and Meroe.

Egyptian Gods

In ancient Egypt, the gods themselves were called *netjer (ntr)*, a hieroglyph represented as a staff with a cloth. While no word for religion exists in ancient Egypt, the concept is expressed abstractly through the term *dsr*, or the sacred, as well as the *mdw-ntr*, or the writing of the gods. The ancient Egyptian writing system in its pictographic form was the means by which the oral stories of the origin of the gods were preserved and their symbols represented. In a sense, art and writing were one in ancient Egypt, and the gods were given immortality through the carving of hieroglyphs on temple and palace walls.

Ancient Egyptian worship was not only polytheistic but also theologically diverse throughout its history. According to mythology, the oldest Egyptian deities were created through bodily fluid (spitting, sneezing, or masturbating), while the later gods of the pantheon were engendered as their offspring. Multiple gods and goddesses with a multiplicity of names were worshipped daily in various geographic areas throughout ancient Egypt. While the sacred triad at Memphis was Ptah, Sekhment, and Nefertem, at Thebes it was Amun, Mut, and Khonsu, and at Abydos it was Osiris, Isis, and Horus. These deities in all their diversity, often depicted in familial constellations (two adults and one offspring), served systematically as anthropomorphic representations of the various dimensions of the life cycle. The dialectic conflict of two forces—*maat* (order) and *izfet* (chaos)—was at the center of the mind of ancient Egypt.

Such theological diversity is also evident in the mythological streams of the origin of the gods known as cosmologies. The most common cosmology, for example, speaks of the begetting of the original nine deities known as the ennead of Heliopolis. In this myth, the original creator Atum emerges into existence on a mound from the midst of watery chaos and spits Shu and Tefenet, his offspring, into existence. Shu and Tefenet engender Geb (earth) and Nut (sky), and Geb

and Nut in turn produce Osiris, Isis, Seth, and Nephthys. Another creation stream originating at Hermopolis begins with a procreative force of eight gods, the *ogdoad*, and these gods produced an egg that produced all living life. Finally, and probably most interesting, is the creation tradition at Memphite. In this tradition, and much like the creation in Genesis 1, the god Ptah creates life through an act of speech.

Daily religious life in ancient Egypt was infused with official, state, funerary, and personal worship. Official or normative religion was comprised of rites and festivals that were performed daily and also yearly. The official duty of the king was to care for the cult statue of the god, which was housed in the temple. Multiple hours throughout the day, the king, or more likely the high priest acting on behalf of the king, would draw the bolt of the door of the temple shrine and enter into the presence of the cult statue to feed, cloth, and care for the needs of the deity. In return, the god would not withdraw his face from the land of the pharaohs and would maintain and restore *maat* throughout the kingdom. In this sense, the king, whose office was divine, served society and cult as the intermediary between humanity and the divine. Similar to the metaphor of the good shepherd in the ancient Near East, the king's primary duty was to care for his subjects.

Most gods began their rise locally, but some were elevated to universal status and were worshipped throughout all the land of ancient Egypt. Such state gods include the Memphite Ptah, the Theban Amun-Re, and Re-Horakhty from Heliopolis. Most of the other gods were worshipped locally at town temples, while the fate of some over time was mere assimilation or even extinction. Since it is virtually impossible to construct broad categories of ancient deities without reducing their complexities, the most frequently mentioned Egyptian gods and goddesses are described with particular reference to the iconography of the deity, the personality and purpose, and the cult center of worship.

First known as a primordial deity, Amun becomes one of the deities of the Hermopolitan system whose epithet is "the hidden one." He is often depicted with a crown of feathers. In the New Kingdom (2000–1360 BCE), he combines

with Re to form Amun-Re, an amalgamated supreme deity who encompasses all creative aspects of the divine.

In the mythology of Osiris and Seth, Osiris falls victim to death by his murderous brother Seth. He is often portrayed in Egyptian art with the crook and flail and serves the gods as the ruler and judge of the underworld in the Book of the Dead. He is associated with kingship in the netherworld and is a universal god. His cult center was at Abydos. Isis, the wife of Osiris, serves as a guardian and magician and is a member of the Heliopolitan Ennead. She too was universally worshipped throughout Egypt.

Horus, the son of Osiris and Isis, is the god of kingship and represents the incarnated pharaoh. He appears in many local forms, and like his parents he is a member of the Heliopolitan Ennead. He represents order in contrast to Seth, his brother, and is frequently depicted as a hawk.

Seth, the murderer of Osiris in the myth of Osiris, represents antiorder, or chaos, and is a member of the Heliopolitan Ennead. Seth was mostly worshipped in the eastern delta and was considered lord of the foreign lands. While he is often depicted as a fantastic human-headed animalistic composite creature representing the forces of *izfet*, the visual representation of Seth is unidentifiable.

The god of writing and the moon, Thoth, is depicted with an ibis head. He was worshipped at Hermopolis and is often found in scenes from the Book of the Dead in which he is recording the weighing of the heart in the judgment scene of the deceased.

During the reign of the Eighteenth Dynasty pharaoh Amenhotep IV, more commonly known as Akhenaten, the divine sun disk, the Aten, was elevated as the god of worship. Akhenaten's elevation of one deity over the other gods was short-lived, but he introduced monotheism, or pseudo-monotheism, into the ancient world, drastically shocking ancient Egyptian theology with the sole worship of the Aten at the city of Amarna.

The main creator god of the Memphite creation tradition, Ptah, created the world through the spoken word.

Canaanite Gods and Goddesses

Archaeological excavations since 1929 at the ancient Canaanite city of Ugarit (Ras Shamra) along the northern Syrian coast have revealed thousands of cuneiform tablets written in Ugaritic, the oldest complete alphabetic script. In these tablets, scholars of the Ugaritic language have translated rituals and offering lists, economic and administrative texts, and mythological and religious literary cycles, all of which have aided such scholars in the reconstruction of the Canaanite pantheon from the second millennium BCE onward. The more important tablets are a series of short stories, or cycles, that depict the gods in mythological pursuits. These include the Baal Cycle, Aqhat, the Kirta epic, and stories about El, the chief deity of the pantheon. From the textual evidences, the gods and goddesses of Canaan are promethean yet anthropomorphic in their stature, and their personalities and problems represented in the cycles mirror the very human conflicts on earth. The mythological and religious archives from Ugarit depict a changing pantheon that was neither static nor fixed but dynamic and fluid.

The chief deity of the Northwest Semitic pantheon, El (literally the Semitic word for God), is the father of Baal. In the literary texts, his epithets include "the King" and "Father of the Gods." He dwells in a tent on a mountain at the base of which flows two fertile rivers. Although he is often depicted as a dignified benevolent

Bas relief depicting El, father of the gods, with a priestess. Serpentine stele, Late Bronze Age, from the acropolis at Ugarit (Ras Shamra), Syria. (Erich Lessing/Art Resource, NY)

and bearded patriarch, this image is contradicted by one Ugaritic text that depicts him as an impotent drunkard. Nonetheless, the remaining Ugaritic archives paint a literary picture of El as the trusted father of the pantheon who serves the other gods and goddesses.

Baal, popularly known from the Old Testament, is the younger and more dynamic deity of the Northwest Semitic pantheon, in contrast to the aging El. Baal's Semitic title means "Lord," and he is depicted in the Baal Cycle as a major contender for head pantheon, rapidly advancing as ruler of the gods. He is depicted iconographically on a stele from Ras Shamra with a club and lightning bolt and is portrayed similarly in the texts as a storm god wielding the natural elements of clouds, wind, and rain. His complexity as a deity ranges from his associations with fertility and agricultural cycles to his participation in the divine battles against the sea and death gods, Yamm and Mot. Archaeologists have found

a temple dedicated to Baal at the archaeological site of Ugarit, a fact that attests to his worship and reverence by the Canaanites. He is frequently depicted as a false and illicit sexual deity in the prophetic books of the Old Testament (I Kings 18).

Dagan, probably a grain god, is found throughout the Northwest Semitic pantheon including the cities of Ebla, Emar, Mari, and Ugarit. Although there are no myths found to date to chronicle his rise and fall in the pantheon, he is attested in offering lists and administrative archives from Ebla as early as the Late Bronze Age. He is mentioned frequently in the book of Samuel (especially 1 Sam. 5–6) as the object of worship of the Philistines, who have adopted him from their Canaanite predecessors.

Although the largely patriarchal world of the Canaanites dominates in the mythological texts, the role of goddesses such as Asherah, the consort of El, as the queen of the gods cannot be overlooked. Like Baal, she is often associated with fertility. She is often identified with Astarte, the Phoenician goddess of fertility and reproduction, and serves the gods as queen mother.

Anat, a warrior goddess with a ferocious temper, is the adolescent sister and consort of Baal. In the myths, Anat frequently crosses gender and social barriers in her endeavors to save Baal from Mot (death).

Kothar-wa-Hasis is a minor deity who serves as the great craftsman of the gods. He lives far off in Crete or Egypt and serves as the inspiration for artisans and craftsmanship. He serves Baal by supplying him with two weapons to defeat Yamm (sea).

Minoan Deities

The earliest known possible representation of a goddess in the Minoan repertoire is the so-called Goddess of Myrtos from Room 92 of the Early Minoan II settlement of Myrtos Fournou Koriphi. The presence of this image, the presence of a bench structure, and the proximity of storerooms suggest that Room 92 was a shrine. The figurine is a hollow, bell-shaped image with a long, solid neck; tiny head; molded breasts; and spindly arms holding a water jug. Paint decorates the body with what appears to be a skirt, a necklace, and a pubic triangle. Although this piece looks like a kindergartener's arts and crafts project, its identification as a deity is based on the thin neck and other nonrealistic attributes, in contrast to Early Minoan images of humans, which were basically realistic. The weird appearance puts the female outside human realms, thus, divine. Furthermore, the fragile yet unbroken condition of the figurine indicates that it could not have been useful for any "practical" functions.

Another possible goddess image is a figurine from a funerary complex at Koumasa dating between the Early Minoan III and Middle Minoan I periods. This is a stylized image with a simplistic head and a trapezoidal body, molded breasts, and painted clothing. Of special interest is the roll of clay around the figurine's shoulders, which may represent a snake. As snake goddesses were common in the later Minoan repertoire, this may be the earliest portrayal of one. The fact that an early version of a snake tube was also found at the site seems to confirm this identity, as snake goddesses and tubes usually came in pairs.

Four more possible goddess images come from the Middle Minoan. Two of these come from Phaistos—an offering table and a fruit bowl, each of which feature two females with somewhat bird-like beaks dancing on either side of some manner of supernatural female creature. The other two Middle Minoan images are the faience "snake goddesses" from the Temple Repositories at Knossos. Further examples of Minoan goddess iconography are present in glyptic art, scenes that appear on jewelry such as signet rings. It would appear that the Minoan goddesses

➤ MINOAN SACRED OBJECTS

The Minoans had many objects that they understood to be divine; their presence on an object or in a picture indicated a religious context or setting. Three of the most important of these were labrydes, horns of consecration, and baetyls. A labrys (sing.) is a double-headed axe. How it came to be a sacred symbol is still in debate, although some suggest that it was because of its use as a sacrificial weapon. This image appears in several media and sizes in a wide variety of religious contexts on Crete. The Arkalokhori cave sanctuary produced dozens of fine labrydes in gold, silver, and copper/bronze sheet metal. Images of labrydes appear on art ranging from gold signets to pottery.

Real (i.e., functional) labrydes have come to light in caves, shrines, villas, and palaces. The palace of Knossos, with its elaborate and confusing architecture, was specifically known as the Palace of the Double Axe, leading to the modern word “labyrinth.” Artistic representations offer only a few clues as to the use of these objects (assuming they had a specific use). There are no portrayals of anyone killing anything with a double axe. There are, however, images of either goddesses or priestesses holding aloft labrydes in either hand or of labrydes standing upright during rituals. The fact that labrydes were erected in Minoan shrines is supported by the presence of stone bases with holes for axe shafts found in a number of sacred sites as well as by depictions of labrydes on Knossian frescoes.

Horns of consecration are U-shaped images that began to appear in Minoan iconography in the

Middle Minoan period. The U shape is understood by scholars to be a stylized rendering of a bull’s head with horns, thus the name “horns of consecration.” Another possible origin is that they represent a valley between two mountains, an image from Egypt. Although horns of consecration started out as smallish images on vases and altars, by the Late Bronze Age they existed in three types: monumental, medium decorative, and miniature. The only monumental examples come from the palace of Knossos and its related peak sanctuary at Mt. Jouktas. Medium horns of consecration (4 inches to 3.2 feet [10 centimeters to 1 meter] high) come from palaces and mansions in central and eastern Crete. In general, no more than two examples come from any given context; usually only one is found. Miniature examples appear in vase paintings and in glyptic representations. Even in the glyptic art, their presence tended to be associated with architecture, suggesting that some of the miniature versions depict the monumental ones.

A baetyl is a nonrepresentational depiction of a deity, usually a stone. The word comes from the Semitic languages and means “house of God” (*beth* = house, *el* = god). Several pieces of Minoan glyptic art suggest that such images played a role in Minoan worship. In some instances, worshippers, often nude, appear to be embracing baetyls, while birds or butterflies (perhaps manifestations of the deity) float nearby. A possible baetyl is located in the west court of the palace at Mallia, where the baetyl may have served in rites of epiphany (appearance of the deity to humans).

—Stephanie Lynn Budin

were associated with flowers, trees, snakes, monkeys, and even birds—in short, they were nature goddesses. But, we must remember that for the Minoans, there was not really a life outside of the natural (unlike today, when people go camping or hiking to “get back to nature”). For the Minoans, to be a goddess of nature implied being a goddess of life, health, sustenance, healing, technology, and the economy.

Until recently, it has been assumed that there were no gods in Minoan religion. However, it has become apparent that there were gods in the Mi-

noan pantheon, although there appear to have been fewer gods than goddesses; there are certainly fewer artistic representations of gods. But these representations do exist, and they tell us something about the male elements of Minoan religion.

One piece of Minoan god iconography is the master impression from Khania. Here is shown a male, nude save for a tight belt, a codpiece, sandals, a necklace, and an armband. He poses in proud fashion holding a staff on what almost resembles a tripartite shrine, except one would

really have to call it a multipartite shrine, since there are so many levels and architectural elements. Many of these elements are capped with horns of consecration, suggesting a religious orientation. Below the architecture is what appears to be a beach, and at the bottom of the seal there is water. In short, the god stands upon a city that is located on a beachfront. The male's size in relation to the city identifies him as a deity, as does the fact that he stands between two horns of consecration. All this shows his dominion over the city with its adjacent beach. Judging from this, it appears that we have here a city god, owner and protector of the urbs (city).

Perhaps the most important piece of Minoan god iconography is the Palaikastro Kouros, a chryselephantine (gold and ivory) statuette from Palaikastro. The statuette is one-half meter tall and stands in a standard worship pose for Minoan males. Rather than a worshipper, though, this image appears to be a god. This is evident first in the materials used in its construction. Both the gold and the ivory had to be imported, probably from Egypt. Such precious materials were probably reserved for divine images; male votives were made of clay. The elaborate workmanship that went into making the Kouros also speaks for its importance, thus its divine nature. In contrast to the rather rude votive images from Crete, there is exceptional anatomical detail in the Palaikastro Kouros, even down to the veins in its arms. It appears that the Palaikastro Kouros is a cult image of a Minoan god.

Some data about Minoan religion can be derived from the Linear B tablets: specifically, the deities' names and where they were worshipped. Linear B tablets come from Mycenae, Thebes, and Pylos on the mainland, and from Knossos and Khania on Crete. A handful of divine names appear on tablets from both the mainland and the island: Zeus, Poseidon, Ares, Dionysos, Dri-mios, Diwiya, Hermes, and Marineus (thought to be some manner of wool god). Otherwise, the deities mentioned were specific to either the Minoans or the Mycenaeans, and it is here where we derive some information about Minoan religion from the tablets. Names specific to the Knossos archive are Atana Potnija, Potnija Dapurito, Pade, Qerasija, Pipituna, Eluthia, Erinus, En-

ualios, and Paiawon. In spite of the odd spellings, many of these names are familiar to the student of Greek mythology. Eluthia is probably Eil-eithia, goddess of childbirth. According to the Linear B tablets, this goddess had a cave sanctuary near Amnissos, where she received, among other things, dedications of honey. Erinus may refer to the Erinyes, also known as the Furies, those dread goddesses who punished crimes against blood kin. Enualios is a later epithet for Ares, just as Paiawon becomes an epithet for Apollo in his healing aspect; both may have been Minoan deities absorbed/replaced by Greek gods. Potnija Dapurito is the Mistress of the Labyrinth, probably a goddess associated especially with Knossos. Atana Potnija is almost certainly Athena, the Mistress of Athens. Finding this goddess in Knossos but not on the mainland is particularly surprising, suggesting that there was probably more overlap between the deities of the island and the mainland than the tablets reveal.

Mycenaean Deities

The clearest evidence about the Mycenaean pantheon lies in the Linear B texts. Only a handful of the deity names in these texts appear both on the mainland and on Crete. We might consider those deities mentioned only on Crete as being Minoan. For those deities mentioned on the mainland, we have at least two possibilities. On the one hand, they may be Greek, meaning that they may derive from the Indo-European civilization that gave rise to the Greek language. Some divine names do have Indo-European etymologies and cognates. On the other hand, they may be pre-Greek, belonging to the indigenous population of Greece before the Greek speakers arrived. These deities may then have been adopted into the Greek pantheon. Some gods do have a blatantly Indo-European heritage, such as Zeus and Poseidon. Others are more difficult to determine.

The deities attested to among the Mycenaeans are Zeus, Poseidon, Ares, Dione, Marineus, Hera, Artemis, Hermes, Dionysos, Posideia, Trisheros, Manasa, Pereswa, Dopota, Dipsioi, Drimios, Iphe-medeia, the Mother of Animals, the Queens, the King, the Lady of Upojō, the Lady of Asiwia, the Lady of Iqeja, the Lady of Newopeo, and the Lady of Grain as well as simply Lady (Potnia). Much can be learned from these names not only about Mycenaean religion but also about continuity of Greek religion into the historical periods. Many deities, such as Hera and Hermes, remained in power throughout Greek history, showing that the Greek Dark Age was hardly the utter devastation and re-creation of Greece that scholars

originally believed it was. Other names in the corpus either ceased to exist after the Bronze Age or morphed into nondivine titles, such as Dipsioi, "the Thirsty," possibly referring to the dead.

Most Mycenaean iconography takes after the Minoan. Nevertheless, some elements of Mycenaean iconography are distinct. Two especially prominent Mycenaean icons are the tau, phi, and psi figurines and the Warrior Goddess. The tau, phi, and psi figurines are named after the Greek letters that they most resemble. Tau figurines (τ) have simple straight bodies with arms extended to the sides; psi (ψ) have similar bodies to the tau but with arms curving out and up on either side of the head. Phi (φ) figurines are discoid in the torso. All frequently have small applied breasts and are clearly female. They began to appear by the Late Helladic IIB period and derived from a simplification of Minoan iconography. This is clearest in the phi figurines, which are a simplified rendering of a Minoan stance of prayer and possibly ecstasy, where the worshipper holds her arms around the body. The psi figurines were also derived from Minoan iconography, especially the Minoan Goddess with Up-raised Arms. All three varieties of figurines were quite crude. The faces were extremely simplistic, and decoration consisted of painted vertical stripes. It is only because they showed up in shrines as well as in graves and households that scholars believe that these common images represented goddesses.

Goddesses were not totally devoid of weaponry in Minoan iconography. Some divine females were shown wielding swords in glyptic representations. But goddesses with prominent weapons and armor become more blatant in the mainland imagery. In one instance, a large-scale goddess appears on a shrine fresco at Mycenae. Only her feet are preserved, but the white paint of the flesh indicates that she was female. Extending down to her toes is the point of a sword with a fuller; its proximity to her body indicates that the goddess is holding the grip. Such imagery is also reflected on a plaque from Mycenae that, like the fresco, dates to the Late Helladic IIB period. This painted plaque, partially preserved, shows a white-skinned being in the center. The fact that she is a goddess is emphasized

➤ WHAT'S IN A NAME? PROBLEMS IN INTERPRETING GREEK DIVINE NAMES

Much of our knowledge about early Greek deities comes from the study of names, which is often a frustrating task for historians. The most vexing of these is the name/title Potnia. By Homer's day, the term meant "revered female," referring either to a mortal or to a goddess. Sometimes the title was specific, as with the Potnia Theron (Mistress of Animals), used in reference to Artemis. The question of who the Bronze Age Potnia was/were, however, is problematic.

The name/title Potnia appears 12 times at Pylos, 5 or 6 times at Knossos, 3 times at Mycenae, and once at Thebes. Thus, it is common to both Greece and Crete. In some instances, the word appears alone; in others, it is modified by a concept or place-name. At Knossos we have the a-ta-na-po-ti-ni-ja, which translates to something like Lady of Athens, and the da-pu-ri-to-jo-po-ti-ni-ja, or Lady of the Labyrinth. At Pylos we have a po-ti-ni-ja-a-si-wi-ja, Lady of Asia, and po-ti-ni-ja-i-qe-ja, Lady of Horses, and at Mycenae there is the si-to-po-ti-ni-ja, or Grain Lady.

The question is whether Potnia is one goddess or many. Is Potnia similar to the Christian "Our Lady," in the way that Our Lady of Lourdes is also Our Lady of Fatima? Or is Potnia a title applicable to several separate goddesses at once? In both linguistics and occurrence, Potnia is related to the god Poseidon. The "Pot" portion of her title may derive from the Indo-European word for "possession" or "ownership," just as Poseidon means "Lord of the Land." Her strongest cult is attested

to at Pylos, where Poseidon was clearly the chief god, and she even has the title of i-qe-ja, relating her to horses, just like Poseidon. One could argue that Potnia was the consort of Poseidon. Furthermore, we know from later Greek mythology that Poseidon once mated with Demeter, both of them in the form of horses. If we add this to our study and combine it with the fact that at Mycenae there was mentioned a Grain Lady (possibly an epithet for Demeter), we might say that Potnia was one universally acknowledged Aegean goddess, understood to be a grain/horse deity and a consort of Poseidon and later manifesting as Demeter.

But then how do we understand titles such as a-ta-na-po-ti-ni-ja, "Lady of Athens," which is certainly a title of an Athena-like goddess? How could an apparently Indo-European word like "Potnia" be identified with a blatantly Minoan term like "labyrinth"? Why does the name/title "Potnia" appear more than once on some Linear B tablets? Should we understand that Potnia, as one goddess, received different dedications in her different guises or that the different Potnias referred to distinct goddesses? In the end, it seems probable that Potnia was a title given to various goddesses in the Aegean pantheons. In some instances, such as at Pylos, one goddess was so prominent that she could be referred to merely by the title "Lady." At other times, adjectives were used to differentiate among goddesses.

—Stephanie Lynn Budin

by the small altar directly before her. She holds before her body a giant figure-eight shield and carries what appears to be a sword in her right hand. Two women stand on either side of this goddess, presumably helping her to arm herself. Both of these frescoes argue in favor of a prominent Warrior Goddess revered in Mycenae, possibly some manner of Athena forerunner.

Mesopotamian Gods

In the present era it is nearly impossible to construct a comprehensive history of ancient Mesopotamian religion because of the cultural and intellectual barriers that divide the ancient-modern mind; however, Assyriologists and other specialists of Near Eastern culture have constructed an almost complete picture of the ancient world of the Mesopotamian gods from archaeological and textual sources. These sources for the present state of our knowledge of Mesopotamian religion include material culture, such as stele, cylinder seals, palatial and temple reliefs, ceramics and other public monuments, and written sources, such as cuneiform tablets written in various genres of Sumerian and Akkadian from the three millennia. Of the more significant literary genres important for the study of Mesopotamian gods and goddesses are the hymns and prayers.

In Mesopotamia, the representation of the gods mirrored the very political office of kingship on earth. Gods were often depicted gathering together at heavenly banquets while debating and working out the problems of Mesopotamian government. Like the earthly kings who worshipped them, the gods dwelt in individual houses, or temples, of their own city-states. In this respect, religion and politics were inseparable in ancient Mesopotamia, and kings and scribes used religion and the gods to advance their political positions. When Hammurabi took the city Babylon as his seat of power, for example, he likewise elevated the status of Marduk, a lesser-known deity, above the other gods. And when the Assyrians in the first millennium made Assur their political capital, the god Assur was exalted as the national god.

Although there is no word in the Mesopotamian cuneiform languages for religion, the gods of ancient Mesopotamia were designated by the

cuneiform signs *dingir* in Sumerian and *ilu* in Akkadian. Both words are translated as "god" or "divine being." In pictographic Sumerian the sign is an astral star, probably linking divinity with the highest level of the heavens. For the ancient Mesopotamians, then, the "sacred" was the collection of many personalities, or divine beings. Known as polytheism, Mesopotamian religion organized its divinities into a pantheon of at least 1,000 to 2,000 deities. Such deities were indeed free from human toil but were also depicted in very anthropomorphized ways. Like humanity, gods ate, drank, often intervened in human affairs, and sometimes behaved badly. In this entry, the dominant Mesopotamian gods and goddesses are surveyed with the focus on their character, fate, and individual personalities.

In Mesopotamian literature, An (or Anu) is the patriarch and founder of the earliest pantheon. Begotten of Anshar and Kishar, he is the source of vegetation with the responsibility for granting earthly kingship. Although archaeologists have found a temple devoted to him at Uruk, it was indeed the case that by the third millennium he was largely removed from the cultic sphere and played little role in the daily life of the Mesopotamian.

By the third millennium, Enlil succeeds his father An as head of the pantheon and is bestowed with sovereign authority. Enlil's exercise of power is acknowledged in the *Epic of Gilgamesh*, the Tale of Anzu, and the *Epic of Atrabasis*. Enlil decrees kingship and controls the position of deities within the pantheon. He wields the weather and often is perceived as the destructive force of the wind. Archaeological evidence supports the textual attestations that his earthly abode was in Nippur, the chief religious city of Mesopotamia in the third millennium.

Although An and Enlil were conceived of as the heads of the pantheon in Sumer, other deities play prominent roles as well. The god of wisdom and magical arts (divination and omens), Ea (Sumerian Enki), is exceedingly cunning and crafty, serving as the intelligent advisor to Enlil. Along with An and Enlil, Ea completes the triad of principal deities in Mesopotamia. Attested most often in hymns, Shamash (Sumerian Utu), the sun god, is the god of omens and law. The offspring of Nanna, the moon god in Sumerian,

and brother of Nana, as well as the son of An or Enlil in Akkadian, Shamash serves to illuminate humanity and testify to all things, including truth and justice. He is depicted visually in the cylinder seals as holding an arc-shaped blade saw with jagged teeth.

Ishtar (Sumerian Inanna), the patron goddess of Uruk and one of the most important goddesses of the pantheon, is viewed as the goddess of love, and her lover is described as Dumuzi. Her marriage is reenacted in the Sacred Marriage rite, a ritual performed between the human king and the goddess. Although numerous traditions regarding her origins exist, the most widely circulated tradition cites her origins as the daughter of An. Other textual traditions make her the daughter of the moon god Nanna (Sin) and sister of the sun god (Utu), while still others cite her as the daughter of Enlil. In the myths Inana and Mount Epih, *Epic of Gilgamesh*, Inana and Bilulu, Inana and Shukaletuda, and Gilgamesh, Enkidu and the Netherworld and Inanna's Descent to the Underworld as well as various hymns praising her, Inana/Ishtar is depicted in three major ways: first, often as a goddess of love with a sexual appetite, possibly connected with prostitution; second, as a powerful warrior-goddess with strong impulses toward violence; and third, as the planet Venus, the evening and morning star. In cylinder seals she is represented as a winged and armed warrior-goddess. Her symbol is a star, and she is sometimes depicted standing on a lion. In Neo-Assyrian visual representations, she is usually nude, depicted with the horns of divinity, and is often called Ishtar of Arbail in Assyrian tablets as a symbol of her warlike nature.

Numerous other mythological stories provide detail about the character and personality of other Mesopotamian deities. In Nergal and Ereshkigal, Ereshikigal, "Queen of the Great Below," reigns as queen of the netherworld. She marries Nergal, the son of Enlil and Ninlil, and dwells in the palace at Ganzir as guardian of the opening to the netherworld. Ninurta, the warrior-god and hero whose initial function was associated with fertility, is the hero of the Tale of Anzu. He is the son of Enlil, and his cult dwelt at Nippur. Neo-Assyrian kings frequently make mention of Ninurta in their annals.

The object of multiple hymns and praises, Marduk was a minor deity elevated by Hammurabi of Babylon in the early second millennium. Marduk's evolution to the head of the pantheon was complete by the twelfth century BCE under the Kassites, when *Enuma Elish*, the epic of creation, was recorded as a mythological account of Marduk's rise in political rule. Like Ninurta, he is a hero-god with cosmic proportions. During the yearly New Year's ceremony, *Enuma Elish* was performed by the procession of a statue of Marduk through the city of Babylon. In Assyria, many of Marduk's traits are ascribed to the god Assur. Supreme god of the Neo-Assyrian empire and sole granter of kingship over Assyria, Assur's evolution and history is vague. In the historical texts, he is exalted to the head of the pantheon throughout Mesopotamia and travels into battle with the Assyrian armies.

Harappan Deities

The Harappan or the Indus Valley civilization is the earliest archaeologically attestable urban civilization in South Asia, which flourished from circa 2600–1900 BCE. Like other great river civilizations of the ancient world (Egypt, Mesopotamia, China), the Indus civilization, whose size is estimated at approximately 386,102 square miles (1 million square kilometers), was highly

advanced. The complexity of this ethnically and culturally diverse civilization is suggested by archaeological evidence that indicates a complex economy, technological achievements (aqueducts, standard weights), markers of urbanization (baked bricks of standard shape, paved streets, urban planning), and cultural products (including a writing system and art).

As the oldest civilization in the subcontinent, scholars have looked to it as the source of culture and religion in South Asia, particularly as the cradle of Hinduism. However, the nature of the so-called religion of the Indus people, which has received the attention of archaeologists, scholars of religion, historians, and other scholars, remains a subject of much interest and debate. One reason for the ongoing debate is the inaccessibility of the written records that have been excavated from the various Harappan sites. Scholars remain unable to identify the language or translate the so-called Indus script, in which the language of the Indus was represented. Without recourse to textual evidence, scholars have depended on material such as seals, sculptures, and architectural structures to conjecture about the nature of the beliefs, practices, and institutions concerned with the world of deities of the Indus people.

The work of Sir John Marshall (1876–1958) and his analysis of Indus religion continues to shape our understanding of a cult of a mother goddess and a great male god occupying a central role in Harappan religion. According to Marshall, the worship of a goddess or goddesses seems to have also occupied an important place in the religious life of Indus people. He reached this conclusion based on the large number of human terra-cotta figurines, both male and female as well as some of indeterminate gender, that have been discovered in Harappan sites. Many of these female figurines, found for the most part in Harappa and Mohenjo-daro, usually wear short skirts, jewelry, necklaces (sometimes neck rings), and various types of headdresses. They are regularly depicted with exaggerated breasts and thighs, which suggested an association of female procreative activity with a concern for fertility. Marshall connected these figurines with a Great Mother Goddess cult found in Baluchistan, Northwest Territory, and other parts of West Asia.

However, several scholars have argued that the evidence for a mother goddess cult as being central to a monolithic Harappan religion is far from irrefutable. It is not certain whether these figurines in fact represented goddess images or functioned as cultic artifacts. Marshall himself classified these terra-cotta figurines into three general types: toys, objects for magical purposes, and mother goddesses.

Another key piece of evidence for our understanding of the religion of Indus is the now famous Seal 420 from Harappa, perhaps the most speculated upon artifact from the Indus civilization. The seal was discovered by Ernest J. H. MacKay (1888–1943) and identified by Marshall as Proto-Shiva. The image presents a male figure seated on a platform with legs bent double underneath, heels together, arms outstretched and hands on knees, and thumbs out in the style of a practitioner of yoga. Marshall further noted that on close examination an erect phallus could be detected but also suggested that the so-called phallus could also represent the end of the waistband that the figure seems to have worn around the waist. The figure depicted is either three-faced or is wearing a three-faced mask and has horns of a water buffalo emerging out of a central headpiece. The seated figure is surrounded by four animals; clockwise from the upper right hand corner of the seal are a rhinoceros, a water buffalo, a tiger, and an elephant. In addition, two other animal figures, identified as antelopes, can be seen underneath the platform.

Marshall's identification of the figure in Seal 420 implicitly draws on parallels from the religious practices of the majority of the population of India, Hinduism, and in particular with the textual history and iconographic elements of the classical Hindu deity, Shiva. The horns of the headpiece are reminiscent in form to one of Shiva's characteristic emblems, the *trishula* (trident). In classical Hindu mythology texts, the Puranas, Shiva is referred to as Mahadeva, "the great god," who is depicted as having three faces with different expressions, as can be seen from the famous sculptures of Shiva at Elephanta Island in Bombay Harbor. The appearance of animals surrounding the seated figure draws a connection with the god Rudra, a minor deity in the Vedas, who has several epithets including

pashupati (“lord of animals”). In the Puranas, Shiva is regularly called *mahayogi* (“great yogi”) and is intimately associated with both eroticism and asceticism. The erect phallus, which may also be visible in other seals illustrating a similar horned-figure seated in a yogic pose, is symbolically connected to the *linga*, the aniconic representation of Shiva in classical Hinduism, which has been analyzed as representing Shiva’s ascetic and erotic/fertility dimensions.

Although Marshall also found further support for his views of Indus religion in the numerous conical objects and ring stones, which he identified as *linga*-s and *yoni*-s, his proto-Shiva thesis has been challenged by several scholars, who posit a Dravidian affiliation for the Indus Valley. Hiltebeitel has suggested that the horned figure represents Mahisha, the buffalo-demon well known from Puranic mythology, who is defeated by the goddess Durga. Parpola has suggested that the seated figure is a seated bull, very similar to those found in early Elamite seals.

Another artifact that scholars have debated as shedding more light on Harappan deities is Mackay’s Seal 13 from Chanhudaro. This seal depicts a short horned bull, identified as *Bos gaurus*, standing over a less clearly identifiable figure, which Allchin identifies as a female figure. The seal shows the bull about to take a female goddess. This scenario is indicated by the bull, with an erect penis, standing on its hind legs, slightly elevated above the female figure, and construes the female’s genitals as being open and exposed, which suggests to him that the female figure is a willing participant in this event. He interprets the scene as a representation of the Father Heaven-Mother Earth motif found in the Vedas.

The interpretations of the archaeological material that has been debated by scholars regarding the gods of the Harappans provided an entry point to access a complex system of beliefs, which remains open to further analysis and debate. Like broader questions of the nature of the religion of the Indus, it remains an open question whether the mother goddess, the great male deity, or even the buffalo cult were Pan-Indus deities or merely reflect local regional cults, and this debate will be shaped by new dis-

coveries in the ongoing excavations of the Indus civilization.

Vedic Deities

Several of the deities in the contemporary Hindu pantheon were known and venerated as far back as the earliest Sanskrit-language text, the Rig-Veda (ca. 1800 BCE). However, it is clear that wholesale shifts in the makeup of the pantheon have occurred since then and that those deities who still remain have changed significantly. Western scholarship has employed a number of different methods for categorizing the Vedic deities: according to their cosmic residence (celestial, atmospheric, or terrestrial), according to their relationship to the four classes of human beings (*brahmana*, *kshatriya*, *vaishya*, or *shudra*), and according to their rank, treating each deity as the highest member of the entire pantheon, each in his turn. What follows is a brief catalogue of the deities who inhabit the Vedic world. They will be ordered here according to the traditional method employed in the books of

the Rig-Veda: Agni comes first, with subsequent deities appearing in order of their frequency of appearance.

The Rig-Veda begins with a hymn to Agni, the god of fire and thus of Vedic ritual. In the opening verse, we are met with a description of one of the primary conceptions of Agni throughout the Vedic canon and ritual system: he is praised as, above all, the god who is the priest of the sacrifice. Agni's primary responsibility, in addition to being present in the three fires of the ritual setting, is to convey the offerings of clarified butter and other vegetal and animal offerings to the gods, even though Agni is also, in other hymns, requested to bring the invited gods to the sacrificial space that has been prepared for them. Thus, unlike many of the other Vedic deities who are associated with warriors, with nature or with morality, Agni is intimately related only to the rites of the Vedic fire ritual.

Appearing more often than any of the other deities is Indra, the god of warriors and of the rains. Indra's rise to prominence came at the expense of the older Vedic deity, Varuna, the Vedic equivalent of the Greco-Roman deity Uranus. Indra is frequently invoked by warriors who are on their way to battle, and sometimes opposing generals are shown invoking him simultaneously. But veneration of Indra in the Rig-Veda does not go uncontested; we see in one Vedic hymn a defense of Indra against those who say "He does not exist," with the refutation "He, my people, is Indra." One of the most famous stories in the Rig-Veda is that of Indra slaying the serpent Vritra. This story, while providing a prototype for subsequent and post-Vedic tales of the wars between the gods and the demons, establishes Indra's second function as the god of the rains. His defeat of Vritra let loose the summer monsoon rains that remain necessary to this day for the agricultural sustenance of South Asia. In some regions of contemporary South Asia, Indra continues to be annually celebrated for the martial and agricultural benefits he provides.

Soma, like Agni, is both a ritual substance and the deity of that substance. While the identity of this deity remained essentially the same throughout Vedic history, the identity of the substance was quickly forgotten. The substance

➤ THE SEMIDIVINE KING

Although the king was a major figure in the Vedic world and although his body was said to be constructed of and by the gods, he was never precisely deified. It was the Vedic priests who were said to be the gods' representatives on earth, and the king was their primary benefactor. Thus, there was always a degree of tension between the king and the priests, who belonged to different caste groups. It was the responsibility of the king to patronize the priests with gifts, and the priests in turn provided the authority that the king required to rule, often through the production of lineages that stretched back to the gods. This dichotomy between the king and the priests is best seen in the king's inauguration ceremony whereby the priests announce the newly inaugurated king to the people but immediately declare that their own king is King Soma, the deified form of the intoxicating beverage drunk during Vedic rituals. While the king is the one who, through his excessive use of power, "eats" his people and the one whose office is said to be the equivalent of 10,000 slaughterhouses, he is actually closer in nature to the common people than to the priests.

—Michael Baltutis

Soma, a nonleafy stalk that can be pressed for its juice, was originally some type of intoxicant (some have posited that it was a hallucinogenic, others a stimulant) that was pressed out and drunk during Soma rituals; it was also the substance that induced the authors of the Rig-Veda to see and then transmit the text.

These three deities—Agni, Indra, and Soma—are easily the three most important deities of the Vedic period, and they reflect the general content of much of the Vedic canon: sacrifice, war, and material success. While the other deities of the pantheon do not receive the same amount of attention as these three, the hymns in which they occur communicate to their audience important facets of Vedic culture and society. Vishnu, one of the most prominent deities in the classical Hindu pantheon, appears relatively briefly in the Rig-Veda but is credited with the creation of the universe. With his three great

strides, Vishnu marked out the three divisions of the world: earth, middle atmosphere, and sky. In later Vedic texts, Vishnu is said to reside in the thunderbolt (*vajra*) that Indra uses to slay the serpent Vritra. And throughout the ritual-oriented Brahmana texts, Vishnu is said to *be* the sacrifice itself.

While goddesses do not hold the special place that they do in later Hinduism, a few goddesses are mentioned in the Vedas. The most significant goddess, and the only one to be invited to participate in Vedic rituals, is Speech (*Vac*); more specifically, she is the sacred speech (*brahmana*) of the brahmana priests. Her relationship to the creator god Prajapati carries over to classical Hinduism, where their new incarnations, the deities Sarasvati and Brahma, are also said to be married.

Vedic deities also tend to come in multiples. Thus, we see many groups of divinities, their individuals often unnamed, who are assistants to a more primary deity. The Maruts, a set of eight storm gods, assist Indra in his battles. The Adityas, led by Varuna, are a group of divinities whose members change throughout Vedic history; the same can be said for the eight (or ten) protectors of the directions (*lokapala*). A peculiar subset of multiple divinities is that of dual divinities, two deities whose names are compounded, of which nearly 20 different pairs are mentioned in the Rig-Veda (e.g., Indra-Agni).

While various types of demons are mentioned in Vedic literature, they do not play a major role. Rather, forces of evil tend to be depicted as terrestrial enemies who must be eliminated, thus the emphasis on battle and the weapons of war. The enemies of the authors of the Vedas are *dasyu* or *dasa*, but these have no cosmic counterpart. The role of divine enemy is filled by the abstract groups of *rakshasas* and *asuras*. One of the more concrete instances of a divine enemy is Rudra (“the howler”), who must be kept at bay. Eventually contributing to the person of the Hindu deity Shiva, Rudra invades the sacrifice and is placated with a small portion of the offerings.

The Gods of China

Chinese religion is characterized by a rich hierarchical pantheon of local, regional, and more universal gods including divinized ancestors, Daoist Immortals, Buddhas, bodhisattvas, and a comprehensive divine bureaucracy. However, the vast majority of the gods who remain popular through worship, art, myths, and novels entered Chinese beliefs, practices, and literature in the past two millennia. The gods of ancient Shang and Zhou China were a less ordered mix of ghosts, spirits, gods, and fantastic creatures. Even though not all of these deities were as integrated into a unified system as would later be the case, there was the sense that the Shang high god, Shang Di (Shang-ti), ruled over various nature gods and divine ancestors. One dominant divine ruler with subordinate ministers mirrored terrestrial political structures. Rulers in turn, at least as early as the Shang kings, venerated a high god and a ministry of lesser gods and divine ancestors as an integral part of their political duties. Commoners also sought favors through their offerings, but their practices were more personal than the official state rituals, and they may have been more concerned with avoiding, propitiating, or even exorcizing harmful ghosts, spirits, and demons. In this broad range of gods and spirits, many were located in a specific place or region, most were mortal, and few if any appear to have operated as agents of a moral universe.

Although many of these beliefs and practices of offerings, veneration, and propitiation continued throughout the history of Chinese religions, new or altered gods and spirits have displaced many of the ancient gods in popular consciousness. Even as the ranks of gods multiplied with a surge of moral and relatively universal Buddhist and Daoist deities, familiarity with and veneration for many ancient gods and spirits decreased as their legends were lost, altered, or fragmented. The ancient gods are rarely depicted, and the

Nüwa mending the sky. Originally drawn in the seventeenth century by Xiao Yuncong. (Yang Lihui. Rethinking on the Source Area of the Cult of Nüwa, 1999)

distinctions among early gods, nature spirits, mythic animals, and extraordinary humans are often unclear. In fact, some of the gods popular after the Han dynasty are rooted in earlier animal and nature deities, but their transformations over centuries, or even millennia, require diligent scholarship to recover their more ancient origins.

There are numerous difficulties accessing the gods and mythical past of ancient China due to the fragmentary myths that have been transmitted, compounded by the problem of transmitters historicizing ancient gods and various fantastical creatures as essentially human culture heroes and sage kings. Thus, an exploration of gods in ancient China requires surveying the overlapping categories of gods, fantastic zoomorphic beings, culture heroes, and legendary sage kings.

The earliest culture heroes retain their extraordinary powers and divine status more clearly than do later sage kings. The Three Sovereigns—Fuxi (Fu-hsi), Shennong (Shen-nung), and Huangdi (Huang-ti)—have been incorporated into traditional accounts of Chinese history as culture heroes of the early third millennium BCE. Their formative roles in the progress of Chinese civilization have been transmitted through legends that include divine and zoomorphic attributes such as the serpent tails of Fuxi, who is famous for taming animals, inventing divination trigrams, and advancing hunting and fishing techniques, and his mate Nu Gua (Nu-kua, Nüwa), a female deity who repairs the cosmos and creates human beings. The agricultural god, Shennong, remains closely tied to nature in his mythology, and Huangdi, also known as the “Yellow Emperor,” was widely worshipped as a prototypical Daoist immortal and popular god as well as a culture hero credited with introducing writing, boats, silk, carts, medicine, and the calendar.

Culture heroes, gods, and kings associated with later times may have been more prone to historicized transformations from earlier mythic portrayals. Nonetheless, some retain connections to their earlier worship as nature spirits or animal-shaped beings, and they may still manifest related extraordinary abilities. For example, myths of Yao, Shun, and Yu, who are heralded by traditional Chinese historical accounts as exemplary sage rulers of the late third millennium BCE, include references to their shamanic abilities including shape-shifting into animal forms. However, other accounts domesticate their supernatural capacities by placing them into a time line of Chinese civilization and dynastic history where they can be appreciated as paragons of morality and pillars of Chinese culture.

Sacred mountains, long revered as the pillars of the entire cosmos, continue to serve as focal points of religious activity from the meditations and adventures of religious aspirants or the site of temples and monasteries to the home of a vast array of gods and spirits. Terry Kleeman’s article “Mountain Deities in China” describes mountains as deities in their own right as well as being home to various deities including “a frightening collection of freaks and monstrosities.” Mountains as deities exemplify that gods in China are not

➤ DIVINE ANCESTORS AS GODS

In Chinese religion, practices for the veneration of ancestors are almost identical to the burning of incense and to offerings typical for worship of the gods. These categories are in fact permeable, as ancestors can become gods and some of the most popular gods, such as Mazu, were once living family members in human history. In Mazu's case, she was an unmarried woman who died at age 27 in a fishing village in the late tenth century. She was then progressively elevated from a local and then regional object of veneration thought to provide help to seafarers, beginning with her family members, while she was alive and reaching out to an ever-widening number of devotees after death. Her reputation, power, and base of devotees continued to grow over the past millennia, with multiple official promotions in the divine bureaucracy—instigated by state officials and popular devotion—capped by the lofty titles of “Holy Mother in Heaven” and “Empress of Heaven” along with enduring devotion, most fervent in Taiwan and Southeast China today. These overlapping categories of ancestor and god appear to have been true in ancient times as well.

Shang religion in the second millennium BCE emphasized sacrifice (offerings made to gods and

ancestors) and divination (attempts to communicate with gods and ancestors in order to ensure that the offerings were adequate and to receive guidance or assistance). Bronze vessels from the Shang era record some of the sacrifices including communications to ancestors. The Shang Oracle bones provide approximately 200,000 pieces of evidence for this popular form of divination. Nobles appear to have directed sacrifice to their ancestors, and the dominant state practices involved offerings to the ancestors of the Shang kings and to Shang Di (Shang-ti), the high god. Records of sacrifice and divination demonstrate a preoccupation with directing appropriate offerings to the correct ancestor to ward off harm or secure benefits. Shang Di ruled the realm populated by these divine ancestors, although it is unclear whether the high god too may have been understood as a more remote and elevated divine ancestor. The Shang maintained their ancestor worship even after conquest by the Zhou, who displaced Shang Di with Tian (T'ien), their high god who originally may have been their divine ancestor as well.

—John Harding

always anthropomorphic or even in recognizable animal forms. The vast array and supernatural power of deities, ghosts, spirits, and animals inhabiting sacred mountains testify to the diversity and regional particularities of deities in China. However, Kleeman's article also analyzes how integrative and syncretistic characteristics of Chinese religion incorporates this vast array of deities into an overarching popular pantheon in which even the mountains themselves order and define Chinese space in accord with and support of an imperial bureaucratic model.

■ Introduction: Atenism

The earliest known monotheistic or henotheistic religion so far identified is the worship of the Aten disk, which rose to prominence in the Egyptian New Kingdom during the reign of Akhenaten (ca. 1352–1336 BCE). During what was later known as the “Amarna heresy,” King Akhenaten moved his court to the city of Amarna and rejected the traditional gods of Egypt, replacing the worship of Aten (the sun disk) as the official state religion. To what extent Akhenaten limited the worship of other deities in Egypt is debated by scholars. Some scholars argue that this was true monotheism and that Atenism demanded recognition that there was only one god, the Aten disk. Other scholars suggest that Aten worship was merely henotheism, the worship of one god as significantly more important than other deities but while still accepting the existence of other gods. Whatever the case may have been, the Amarna period was one of the most significant moments in religious history, a period of about 20 years when centuries of Egyptian religious traditions were overturned.

—Kevin M. McGeough

Akhenaten

The worship of Aten and the brief movement toward monotheism in Egypt was inextricably linked with the character of Akhenaten, a Pharaoh of the Eighteenth Dynasty of the New Kingdom. Although there is much evidence for the life of Akhenaten, his character and motivations are heavily debated by archaeologists and historians. Akhenaten was often referred to as the heretic king, and later Egyptian kings obliterated his monuments and removed his name from king lists. James Henry Breasted, one of the founding scholars of American Egyptology, once referred to Akhenaten as the “First Individual in Human History” since the personal interests of Akhenaten had such a profound effect on events in Egypt.

When Akhenaten ascended to the throne after the death of his father Amenhotep III, he was named Amenhotep IV. He was crowned pharaoh in Thebes along traditional lines, but not much of his reign could be considered tradi-

tional after this. Soon after, he changed his name to Akhenaten (which reflects his worship of Aten) and moved the capital of Egypt from Thebes to a new city named Akhetaten (modern el-Amarna). Textual sources from Akhenaten's reign describe the “evil words” that Akhenaten, his father, and grandfather heard at Thebes, perhaps an allusion to antimonarchic sentiments in that city.

With Akhenaten's move away from Thebes, he initiated a systematic repression of the worship of other deities. Other gods' names were sabotaged and removed from monuments. Amun's name was particularly desecrated, and there seems to have been significant animosity directed toward this deity in particular. Many scholars have suggested that extreme repression of Amun worship is indicative of one of Akhenaten's motivations for the elevation of Aten to authority as the sole god of Egypt. This may have been an attempt on the part of Akhenaten to stem the growing power of the temple of Amun at Karnak, a religious body that eventually rivaled the pharaohs for control of Egypt. By the Eighteenth Dynasty, the cult of Amun was the most powerful religious force in Egypt and Amun worship the most prominent religious practice in the state cult. Scholars believe that the Temple of Amun was formally closed during Akhenaten's reign, but this is not fully proven. Whether or not the move to Amarna was politically motivated, Akhenaten's belief in Aten as a supreme deity cannot be denied, and religious belief must be understood to be one of the king's key motivating influences.

The depiction of Akhenaten in the art of the period deviates from the typical portraiture of royal individuals. Much of this reflects a change in artistic style that is associated with the Amarna Age. The peculiarities of the depiction are many: exaggerated hips and facial features, thin limbs, and extended stomach. Members of his family are also depicted similarly. Some scholars have suggested that perhaps the odd depiction of the king reflected his physical features, and some have gone so far as to suggest that he had an endocrine disorder that corresponds with those

➤ TALATATS

Talatats are small stone blocks of a standardized size that were used for the construction of Aten temples at Karnak during the reign of Akhenaten. Many of these stone blocks were decorated with segments of Egyptian images that, when put together, depict a larger scene, much like a jigsaw puzzle. After the Amarna Age came to a close, later pharaohs took apart the Aten temples and used them for construction fill. Archaeologists working at Karnak have excavated these talatats and have reconstructed many of the artistic scenes from the temples. This was painstaking work, since tens of thousands of these construction blocks were used in the construction of the temples.

—Kevin M. McGeough

types of features. If Amarna art was meant to be realistic, then this marks a dramatic change in Egyptian artistic styles, which traditionally emphasized idealism over verity. These changes in art appear in paintings, reliefs, and sculpture.

Akhenaten's family was also noteworthy. He was married to Nefertiti, a queen who is well known today because of the stunning bust of her excavated from Amarna. Nefertiti was often depicted alongside Akhenaten and sometimes in a more prominent position, unusual for an Egyptian queen. At Thebes, Nefertiti was depicted in traditional kingly roles (such as smiting scenes) and, from an artistic standpoint, appears to be prominent in Egyptian governance. Yet interestingly, she is not mentioned in Akhenaten's diplomatic correspondence, suggesting that her role in governance, if any, was limited. Akhenaten had at least six daughters with Nefertiti, although some scholars (especially those who believe that he had an endocrine disorder that would have limited his fertility) have suggested that these children were actually fathered by another man.

After the move to Amarna, Nefertiti's importance, at least in the iconography of governance, declined, although what this is indicative of is unclear. In his later years, Akhenaten was also

married to a woman named Kiya and possibly a number of other wives whose names have not been preserved. His successors, Smenkhare and Tutankhamun, may also have been his sons; the names of their mothers have not been preserved. After Tutankhamun's death, the Amarna heresy was brought to an end, and Egyptian religion and statecraft returned to its traditional manifestations.

Aten Worship

Aten first appears in Egyptian Middle Kingdom texts as a word that literally refers to the disk of the sun, the physical disk that one sees if one looks up into the sky. Later, Aten is seen as one manifestation of the solar deity Re. It is in the reign of Akhenaten, and seemingly under the direct influence of that king, that Aten came to be understood as a deity in its own right, although some scholars argue for a slightly earlier appearance of a deity named Aten. Whenever the Aten was first understood to be a deity, it is during Akhenaten's reign that the physical disk of the sun becomes worshipped as the state deity of Egypt and perhaps the only deity of Egypt.

In Amarna era art, the Aten is depicted as a disk in the sky. Rays extend down from the sun disk and terminate in hands. Often these hands reach toward images of Akhenaten and his family—specifically toward their noses—indicating the life-giving force of the Aten. Schlögel has argued that this and other linguistic evidence suggests that it was the light that radiated from the sun

disk that was worshipped. This is also consistent with the layout of temples to Aten, which were unroofed and thus open to the sun.

The worship of Aten marks a distinct break from traditional Egyptian religion in a number of ways. Unlike other Egyptian deities, the direct worship of Aten seems to have been reserved for the king and the royal family. In the “Hymn to the Aten,” it is suggested that only the king could communicate with Aten. The king’s family, especially his wife Nefertiti, was depicted on cult stelae (plaques with images of the royal family in the presence of Aten) that have been found in the private homes of Amarna.

Unlike other Egyptian deities, there was no cultic statue associated with Aten worship. The temples were open-aired, thus allowing the rays of the sun direct access to the sacred space. Because there was no cultic statue, the usual Egyptian ritual practices, such as the feeding and caring for the divine image, were unnecessary and did not play a role in Atenism. Rather, Akhenaten (acting as high priest) and/or his family members would enter the sanctuary and lead ritual services in honor of Aten.

The most significant break with Egyptian traditions, however, has to be in the primacy with which Aten was placed over other gods in Egypt. While the popularity of various gods and goddesses waxed and waned throughout Egyptian history, there was never a situation in which a god was revered with such a singular status. Under Akhenaten, the worship of other gods was suppressed and their names and monuments desecrated, although the extent to which this occurred is not clear. It seems unlikely that people throughout Egypt gave up the worship of other gods on the command of the pharaoh, and so Aten worship likely occurred primarily at Amarna and in Upper Egypt.

➤ MOSES AND AKHENATEN

In order to explain the origins of Hebrew monotheism, biblical scholars in the late nineteenth and early twentieth centuries argued that perhaps Moses had known Akhenaten or had been aware of Aten worship. These scholars further postulated that Moses adapted the monotheistic tendencies of Atenism to Hebrew religion and the worship of the Hebrew God. The father of psychoanalysis, Sigmund Freud, argued in his last book *Moses and Monotheism* that Moses was an Egyptian monotheist who was killed by the Hebrews but that in subsequent years the Jewish population had suppressed this traumatic memory. Despite the appealing nature of this theory, there is no evidence to suggest that any Hebrew populations encountered Akhenaten; the first historical attestation of “Israel” does not occur until centuries later, and the emergence of the Israelites does not occur until the Iron Age.

Life and Worship at Amarna

In the fifth year of his reign, Akhenaten began construction of a new capital city, on virgin soil, and he and his family left Thebes for the new capital. The pharaoh’s new city was called Akhetaten (modern al-Amarna), which means “the horizon of the Aten” and was the center of Aten worship as well. This move marked a radical break in New Kingdom governance and likely reflected an attack on the power of the cult of the god Amun at Karnak at Thebes. This was an abrupt move, so abrupt that the king and his family lived in tent quarters at Amarna while

➤ PSALM 104 AND THE “HYMN TO THE ATEN”

A poem known variously as the “Hymn to the Aten” or the “Sun Hymn of Akhenaten” is one of the most important sources for understanding the theology of Atenism. The poem was preserved in the tomb of Ay, who acted as courtier to King Akhenaten and later became king himself after the unexpected death of the boy king Tutankhamun. It is 13 lines long and may have been composed by Akhenaten himself. Akhenaten is certainly the presumed speaker in the poem.

In some ways, this hymn can be seen as part of a longer Egyptian literary tradition of solar hymns. What makes it different is its treatment of its subject, Aten, which differs from the treatment of solar deities in other hymns. As with other hymns, the “Hymn to the Aten” praises Aten. Yet it also notes the king’s special relationship to the deity, and the tone of the poem is one that borders on religious ecstasy. Aten is also said to be the creator of all, a universal deity. The poem is filled with references to nature, the creations of Aten, and time itself is even understood to be a manifestation of Aten’s creative powers.

What is also remarkable about this particular poem is the amount of similarities between it and Psalm 104 found in the Hebrew Bible. In Psalm 104, the Hebrew God is compared to the sun, and a number of the themes explored and expressions utilized are very similar to those in the “Hymn to the Aten.” Verses 20–26 of the psalm are so similar that they seem to have been directly borrowed from the Aten hymn. Despite the similarities, it is not clear what relationship existed between the two poems, which were composed centuries apart in different languages and locations.

—Kevin M. McGeough

the buildings were constructed (which themselves were built and designed rapidly and to a much lesser level of quality than typical Egyptian royal structures). Motivations for residing at Amarna were primarily connected to the worship of Aten. So after Akhenaten’s death (and the collapse of Aten worship in Egypt), the city was abandoned, and Thebes was made the capital of Egypt once again.

Because Akhetaten was abandoned shortly after Akhenaten’s death, much of the city has

survived for archaeological study and provides a snapshot of life during the “Amarna heresy.” This is one of the few Egyptian sites that was preserved to a large enough extent to demonstrate ancient Egyptian urban planning. Noteworthy are the 14 boundary stelae that mark the “official” extent of the city of Akhetaten. Each stela is inscribed with hieroglyphic text and an image of the royal family worshipping Aten, thus directly demonstrating the connection between the foundation of the city and Atenism.

The residence of the royal family has been discovered, and tombs have been excavated on the outskirts of the city. Only one royal tomb was actually used (presumably the others were not used because the site was abandoned), but a number of nobles’ tombs located in the north were used. The studio of the sculptor Thutmose was also discovered here; the famous bust of Nefertiti was found in this building. It was not meant as a piece of art itself but rather as a study piece for other sculptors to follow, although it is now considered a masterpiece of world art. Along with this more famous piece, a number of plaster casts of other members of the royal family were also discovered here.

The site of Amarna is also the location where the so-called Amarna Letters were recovered. These were diplomatic letters written in cuneiform in the Akkadian language (a Mesopotamian language) that was used as the language of international correspondence at this time. Kings from Mesopotamia, Cyprus, Canaan, and northern Syria all wrote letters that were preserved at the site of Amarna. This correspondence sheds much light on the relationships between states during the Bronze Age.

In one of the Amarna letters, a writer complains that his messengers were forced to stand outside in the hot Egyptian sun. This complaint is consistent with the archaeological remains of the temples that have been excavated at Akhetaten, all of which were unroofed. It is quite understandable why a visitor to Akhetaten would have complained about standing in the unshaded Egyptian sun in the middle of the day; no doubt this architectural design was to allow the Aten to shine its rays directly onto the temple, the people inside the temple, and the offerings presented there.

The largest temple complex at Amarna was the so-called House of the Sun-disk. This was a large walled enclosure that actually contained several temples within. All of the courts of the temples were open to the sky, although there were sun-shades and chapels that allowed some relief from the Egyptian sun. The walls were, for the most part, decorated with reliefs typical of other Egyptian temples. However, the *sed*-festival (in which the king ritually renews his power) was not depicted, suggesting that Akhenaten no longer followed this practice. Another deviation from Egyptian religious norms at the site is that the typical obelisk (representing the *ben-ben* stone, the mound where creation began) was replaced with a round-topped stone on a dais.

Another complex dedicated to Aten was located near the southern cliffs at the outskirts of the city. Donald Redford has called this a “gazebo” for Aten. Called the Maru-Aten, this was a walled enclosure that contained gardens, pools, open-air kiosks, and an artificial island. Inscryp-

tions at the site mention Akhenaten’s daughter Meritaten (and an erased name was likely his wife, Kiya), suggesting that this area may have been designed for their use.

■ Introduction: Temple Architecture and Practices

A popular joke among archaeologists is that if you do not know what an artifact that you have found was used for, say that it had a religious function. This joke reflects the fact that it can be extremely difficult to identify religion and religious practices (normally called cultic practices by archaeologists, without intending any of the connotations that the term “cult” has in modern times). Archaeologists were once not as careful when identifying temples and cultic equipment in the archaeological record. Now there is a growing recognition that it is important to be careful in applying these designations.

In ancient times, cultic structures were not usually intended to be used by all of the worshippers in a community. Unlike a modern church, mosque, or synagogue, an ancient cultic structure was not typically a place for personal worship. Rather, cultic specialists, such as priests, would be in charge of performing the rituals

intended for the deities; this was their job, and they were considered experts in the subject. These expressions of reverence or worship toward the deity were the main foci of temple practices in ancient times. In some traditions, the temple was thought to be the actual house of the deity on earth; in other traditions, this was merely a location where earthly worshippers could gain access to that deity. Often a physical representation of the deity was present in the temple. Archaeologists find statues of the deities, images of the deities, iconography that represents the deities, and even niches built directly into the architecture where the deity may have been thought to be present. These are the strongest pieces of evidence that a particular excavated structure was in fact a temple.

There are a number of other criteria that can be used by archaeologists to distinguish a temple (or other type of religious structure) from other buildings. These structures were often set

off from the rest of the community, since the space was considered sacred. Archaeologists may find walls around the complex or other markers that would have indicated to the ancient population that they were leaving the profane world for the sacred. Within this enclosed space there must be enough room for sacred activities to take place. Sometimes these activities incorporated the architecture of the building directly into the ceremonies, such as when offerings were placed directly onto benches or altars attached to the walls. Other evidence that ceremonies may have taken place include the remains of offerings. Animal bones from sacrifices are found most frequently, and pottery containers that once held libations are also common. The events that went on within a sacred structure can sometimes be accurately reconstructed if textual or artistic records survive that explain what was done. In Mesopotamia, for example, priests kept written records of what was supposed to happen during a ritual. For many other places, we have less direct evidence.

—Kevin M. McGeough

Egyptian Temple Architecture and Practices

The ancient Egyptians built their temples to reflect the ideal universe; every part of the temple was imbued with symbolic meaning corresponding to Egyptian concepts of the cosmos. At its most basic level, Egyptian ideology can be summed up by one metaphor: the eternal fight between order, justice, or truth, known as *maat*, and chaos, known as *isfet*. The purpose of the gods and kings was to bring, restore, and maintain order, or *maat*, to every aspect of Egyptian life. In the Egyptian conception of the universe, Egypt (specifically the Nile Valley) was *maat*, and everything desert or foreign was considered chaotic and evil.

Every architectural element in an ancient Egyptian temple has some mythical and/or religious symbolism attached to it. An enclosure wall surrounded every temple and marked the boundary between the sacred world and the secular world, but on a symbolic level the wall marked the boundary between order and chaos. Inside

the enclosure wall were not only the temple but also priests' houses, gardens, storage facilities, and kitchen facilities for preparing the daily offerings for the gods. On the outside walls of the temple were images of kings defeating foreign enemies and hunting lions and bulls, which depicted the king's triumph over the forces of chaos. These victory scenes are apotropaic, meant to keep the forces of evil out of the temple. The temple's axis, from its pylon, or entrance gateway, to its rear where the holy shrines were located, is oriented on the same path that the sun, the god Re, takes through the sky, from east to west. The pylon is shaped like the hieroglyph for the horizon, with two mountain peaks on either side of a valley. At sunrise, the sun climbs between the two peaks of the pylon. As one progresses through the temple, the rooms get darker until at symbolic sunset, in the sanctuaries, there is complete darkness and the ceiling is covered in drawings of stars.

Beyond the pylon is a peristyle hall, which has rows of columns encircling an open-air court. The peristyle hall represented the land of Egypt, which the Egyptians perceived as having two parts: Upper Egypt (from Aswan to near present-day Cairo) and Lower Egypt (the delta of the Nile). The capitals of the columns in the peristyle hall were in the shape of lotus flowers or papyrus plants. The papyriform (papyrus-shaped) and lotiform (lotus-shaped) columns represented Upper and Lower Egypt, respectively. Installed in the peristyle hall were statues of kings and high officials who wished to take part in the offering cult of the gods. Every level of priest—and on special feast days the public—was allowed into the peristyle hall to present offerings to the gods and statues.

Through a tall doorway and up a ramp or short flight of stairs is the hypostyle hall (a type of hall where pillars support the roof). This hall is completely roofed and is filled with closely packed rows of columns. The columns represent the reeds growing out of the primordial marsh represented by the floor, and the ceiling is covered in a star pattern representing the sky. Dimly lit, the hypostyle hall represents a transitional space between the earth (the peristyle hall) and the mound of creation (the sanctuary beyond).

► THE TEMPLE OF KARNAK AT LUXOR

The temple of Karnak at Luxor is perhaps the most important of ancient Egyptian temples. Karnak was built to venerate the god Amun, who by the Middle and New Kingdoms was considered to be the king of the gods and an important creator god. Karnak temple was established in the Middle Kingdom, but the earliest parts still standing date to the reign of Amenhotep III in the New Kingdom.

The Karnak temple complex is almost 250 acres in area and consists of about 20 temples and chapels all dedicated to Amun, his family, or kings who dedicated buildings to him. Almost every king built something in the Karnak temple complex. Seti I and his son, Ramses II, built a huge hypostyle hall with 134 columns. Queen Hatshepsut erected four obelisks, symbols of the sun god Re, who was often syncretized with Amun. Even the so-called heretic king Akhenaten built a temple within the complex to his god Aten, which was the sun's disk and one aspect of Amun-Re.

The temple of Amun itself is huge in comparison to most temples and has ten pylons (most temples only have one pylon), each of which was built by a different king. The first six are aligned with the east-west axis of the temple and direct the worshiper to the sanctuary in the rear. The other four pylons branch off between the third and fourth pylons and direct the worshiper south to the temple of the goddess Mut (the wife of Amun), whose temple was outside of the Karnak complex enclosure wall. An avenue of ram-headed and human-headed sphinxes leads from the Karnak enclosure wall to Luxor temple, another temple of Amun, that was built to celebrate the Opet festival.

Temple of Luxor at Karnak. (Gloria Euyoque)

Another avenue of ram-headed sphinxes leads from the first pylon to the Nile River and marked the path that the barque of Amun took during the festival of Amun, when the god visited the mortuary temples of the kings located on the west bank of the Nile.

The priesthood of Amun was one of the most important in all of Egypt. In the Nineteenth and Twentieth Dynasties, only two families held the position of high priest of Amun. The high priest of Amun held considerable political power due to the large amount of land controlled by the temple. By the Twenty-first Dynasty, Egypt was politically divided, with two kings ruling simultaneously: one from Tanis in the Delta and the other made up of high priests of Amun ruling Thebes and Upper Egypt.

—Vanessa Smith

Perhaps the most famous hypostyle hall is that built by Seti I and completed by Ramses II in the temple of Karnak.

Past the hypostyle hall, a second smaller doorway demarks the entry to the sanctuary. At each door along the processional route the floor is raised and the ceiling is lowered, symbolizing the journey to the mound of creation. The sanctuary represents the primordial mound where earth and life were created and the chaos of the void was put to an end. The primordial mound is also where the gods themselves were created

and lived before humans were put on the earth. There are usually several rooms in the sanctuary area, each dedicated to a different god. Although most temples were dedicated to a specific god, that god's family, usually his or her spouse and offspring, were worshipped alongside the primary god. The sanctuary is the most sacred part of the temple, only accessible to the king and high priests. It is where the gods lived and where the statues of the gods were tenderly looked after. The walls of the sanctuary are covered in depictions of the king presenting offerings to the

god. The ancient Egyptians believed that writing and art were filled with magical powers; a drawing of a king offering food to a god was akin to the actual offering ritual.

Although there was a standardized form to most ancient Egyptian temples consisting of a pylon, peristyle hall, hypostyle hall, and sanctuary, there was variation in how these elements were realized, especially in the Old and Middle Kingdoms. The earliest temples consisted of an enclosure wall with a square mound on one end, which may or may not have had a sanctuary atop. Most of the known temples from the Old and Middle Kingdoms are mortuary temples, dedicated to a deceased king who at death is transformed into the god Osiris, the king of the afterlife. These temples were often either directly attached to a pyramid or part of its larger complex of buildings. Few gods' temples survive from the Old and Middle Kingdoms because these early temples were dismantled and replaced by newer, larger, and better temples in the New Kingdom. Far from being considered sacrilegious, it was every king's duty to renew and improve the houses of the gods. In so doing the king established his direct relation to the god or gods in question. And because it was that king's image on the sanctuary walls presenting offerings to the god, the king permanently connected his name with not only the god but also the preservation of *maat*, which emphasized the effective rule of that king.

The ancient Egyptians considered the state and religion to be irrevocably linked. As the embodiment of the god Horus on earth, the living king was the intercessor between the divine plane and the mortal world. In theory, only the king could act as the caretaker of the statues of the gods, but with so many temples and so many gods this was not practical. High priests acted in the king's stead, performing the daily offering rituals and officiating at festivals. Except for high priests, the position of priest was not a full-time job. Men and occasionally women from the upper classes spent several months a year serving as priests and the rest of the time in the military, royal court, local government, etc. There were several different levels within the priesthood, and each level was responsible for different duties within different parts of the temple. Only a very

few high-ranking priests were ever allowed in the sanctuary to conduct the daily ritual. Most priests were in charge of cleaning the temple, purifying the offerings, or handling other non-ritual duties. There were very strict rules concerning the purity of each priest while on duty; the priests had to bathe often, shave their heads and bodies, abstain from sexual activity, and not eat certain foods that were considered unclean.

The daily temple ritual helped to restore and retain *maat*, the order in the universe, through the worship of the divine statue. The day began before sunrise when the king or high priest bathed and ritually purified himself. At sunrise, the sanctuary door was opened and light was allowed to enter, and incense was burned to purify the air. The king or high priest entered the sanctuary and opened the shrine, which held the divine statue. The veil was removed from the face of the statue, and the king or high priest knelt before it, intoning hymns of adoration. The statue was removed from the shrine, and the shrine was ritually cleaned. The statue was then bathed, oiled, clothed, and adorned with jewelry, and cosmetics were applied. The divine statue was replaced in the shrine and was offered wine, beer, and trays of food. Once the statue was sated, the food and drink were removed for redistribution to the priests (priests were paid using these food offerings, as the ancient Egyptians had no monetary system). Then the shrine was closed and sealed, and finally the door to the sanctuary was closed. This daily ritual occurred as many as three times a day but usually only once.

The ancient Egyptians celebrated numerous festivals that were related to astrological, mythical, or seasonal events. During the festival, the shrine of the god with the divine statue inside was placed on a barque, or boat, that the priests carried. The god was then carried either to the peristyle hall or out of the temple. On some occasions the god would travel to a different temple to visit another god. The festivals allowed the people to view the god, celebrate the bounty bestowed by him, and ask for the god's favor. When a god ventured out of his temple, he could directly intercede in the mortal world by acting as an oracle. People would ask questions, and the movement of the barque would indicate either a

positive or negative response. Other festivals involved the staging of mystery plays in which certain episodes in the god's mythology were acted out. On festival days the temple made additional food offerings, which were often distributed to the people as a form of charity.

Places of Worship in the Bronze Age Levant

Places of worship in the Bronze Age Levant have been of particular interest to researchers of the Hebrew Bible. Given that this is the region where Israel would later emerge and where many of the narratives from the Old Testament take place, it is no surprise that scholars of the Old Testament hoped to find direct biblical connections. Now, the study of religion in the Levant has become a scholarly discipline in its own right, and archaeologists have identified a long tradition of religious activity, primarily through religious architecture and structures.

The site of Gilat, located along the Wadi Patish northwest of modern-day Beer Sheva, provides some of the earliest evidence for cultic architecture and public worship. The cult center includes a large complex comprising several buildings that appear to have served as some form of cultic center. The cultic area incorporates open courtyard space and several buildings, including Room A, which had a high concentration of symbolic items, including more than sixty "violin-shaped" figurines. The site of Teleilat Ghassul also featured a cultic center (Area E) with several temples. Vivid murals were painted directly onto plastered walls using a variety of materials for pigment, including red ochre. Other motifs seen in the murals include a schematized star, several

human figures with pronounced eyes, and a horned animal. At both Gilat and Ghassul, the temples were in use over a considerable length of time. Another cultic complex, at En Gedi, included four separate structures and a large open-air courtyard. This site is located on a high cliff overlooking the Dead Sea, far from any settlement. Open-air sanctuaries made up of large, walled, circular enclosures and *massebot*, or stele-like standing stones, have been found throughout the Sinai and Negev. Based on their form and location, it is thought that these served the pastoral transhumant population.

There is little evidence for cultic architecture at the beginning of the Early Bronze Age, with the major exception of Megiddo. By the mid Early Bronze Age, however, places of worship appear at a number of large centers. The basic plan for Early Bronze Age cultic architecture is traditionally known as the "broad room": a rectilinear structure with an entrance near the center of the long side. Over the course of the period, temples generally increased in size and scale, and there were elaborations on this basic temple plan, such as at Megiddo. A large structure at Erani, with nine pillars lined in three rows, has also been interpreted as a temple. Plaster-coated walls were also found at a temple at Yarmuth, hence the name, the "White Building." A raised platform opposite the entrance may have been used for rituals and/or to support a cultic figure. Cultic installations and features included raised platforms and large, flat *massebot*, which often appeared in groups, as seen at Hartuv. It is not clear what their function was, though they may have represented deities.

One recurrent motif from the seal impressions depicts a group of figures with arms interlocked, perhaps engaged in a dance. In at least one example from an EBIII jar, the dancers appear above a row of rectangles that recalls the "palace facade" motif, known from many seals, suggesting public ceremonies involving dance. Dancing may have played a vital role in rituals associated with the harvest, and it is possible that in this instance the dancers performed in or near some monumental structure, such as a temple. At Bab edh-Dra, one scene shows four figures with upraised hands, bracketing what may be a palm branch.

► THE LACHISH FOSSE TEMPLE

The site of Lachish hosted the “Fosse Temple,” a unique example of religious architecture standing just outside the city wall in the Middle Bronze Age moat. This temple had a small entrance corridor leading to a main hall with rows of wooden columns, and though it was rebuilt several times during the fifteenth to thirteenth centuries BCE, the plan remained largely the same. The floor of the thirteenth-century temple, which saw violent destruction, was permeated by *favissae*, small caches of valuable goods (for example, an ivory statue). A building similar to the Fosse Temple has also been found at Tel Mevorakh, and it is possible that these unique temples represent a separate current of ritual practice distinct from the main Canaanite cult of the Late Bronze Age.

—Jonathan Golden

The archaeological evidence for religious and ritual activity during the Middle Bronze Age, including burial offerings, sacred deposits, artistic representations, and cultic architecture, is vast. By the later Middle Bronze Age, large temples stood at a number of Canaanite sites, including Tel el-Hayyat, Hazor, Tel Kitan, and Shechem. These imposing structures were built with massive stone foundations that generally followed a plan incorporating one long main hall, though these varied from the broad-room design. One form, the “Migdal temple,” had a symmetrical, direct-axis plan, and there was often a small niche at the back of the broad hall that may have been used for ritual practice or display. One of the best examples of this tradition was the massive Migdal temple at Shechem. The temple had walls reaching up to 5 meters (6.4 ft.) thick and was erected atop a large earthen platform similar in construction to the ramparts, creating an “acropolis” effect.

Several of the basic design elements in the Canaanite temples display a distinct northern influence. The general floor plan of temples in Canaan has parallels with structures found in the great Syrian cities of Alalakh, Ebla (Tel Mardikh), and Ugarit (Ras Shamra), but it is not clear whether this represents the spread of a widely

held belief system or the emulation of architectural style. A similar plan, in fact, was also employed in a temple from Avaris (Tel el-Daba), the center of Hyksos-Asiatic life in the Egyptian Delta. Temples and chapels have also been identified at a number of Middle Bronze Age sites on the coastal plain, including Ashqelon, Tel Mevorakh, and Tel Michal.

Buildings and open courts designated for religious practice were often grouped together within a city, forming cultic precincts. At Megiddo, a small platform mound may have been reserved for cultic activities, while the religious precinct from the Early Bronze Age was transformed into an open plaza with *massebot*. The cultic area at Nahariyah had a similar open plaza, and the open-air site at Jebel el-Rukba in southern Samaria had an oval platform, built of stone, which may have functioned as a gathering place for rituals. *Massebot* have been found at a number of sites, the most outstanding example being Gezer, where the “high place” featured a group of eleven massive *massebot*, which still straddle the mound’s crest today. Byblos, too, featured a cluster of large standing stones.

Despite the fact that Egyptians dominated Canaan for much of the Late Bronze Age, much of the Canaanite religious tradition remained intact, which is not surprising considering that religion is often one place where cultural identities find refuge when threatened. Temples dating to the period have been discovered at several sites, including Beth Shean, Lachish, and Tel Mevorakh. At Megiddo and Hazor, temples originally built at the end of the Middle Bronze Age were used right through to the Late Bronze Age. At this point, both were renovated, but with limited changes to the basic broad-room design, where the main hall was entered via a front porch. Some of these temples contained a small room where access was limited, which probably served a specific cultic function, that is, as “holy of holies.” As during the Middle Bronze Age, these temples had affinities with the temples of Syria. The temples at Ugarit, Alalakh, and Hazor had similar building plans and main halls of similar dimensions, and at Alalakh the temple had lion orthostats and a basalt altar similar to that from Hazor.

Despite the continuation of Canaanite customs, in certain places the Egyptian impact can

be clearly seen in religious practice. A temple at Beth Shean departs from what is typical of Canaanite cultic architecture, being squarer in plan (200 square meters, or about 2,150 sq. ft.) and entered via a bent axis. It also featured benches along part of the wall, and two columns in the center of the hall supported the roof. A “holy of holies” was approached via a seven-stepped staircase, and a small adjacent chamber may have served as a treasury. One of the more unique features at the Beth Shean temple is the use of Egyptian-style papyrus-shaped capitals. This temple was destroyed at the end of the thirteenth century BCE, but it was subsequently rebuilt during the time of Ramses III, this time with an Egyptian frieze. The Egyptian influence at Beth Shean is also reflected in a stele that depicts an Egyptian official performing some sort of ritual or act of supplication before the Canaanite god Mekal, which suggests the integration or fusion of practices.

Early Mesopotamian Temples and Shrines

Probable shrines are apparent in the earliest levels of Mesopotamian sites. A few Ubaid and Uruk buildings have been excavated, the location and contents of which suggest a ritual function. In

➤ THE GOD AT HOME

The temple, known simply as *E/Bitu* (“house”), was both the home and, in some transcendental sense, the embodiment of deity. Within the temple the god was more precisely located within his or her image, made, according to written descriptions, from the most precious materials, including gold covering a wooden core, and clothed in the finest raiment and the choicest jewels. The manufacture and installation of a divine image was a major event, undertaken as a pious duty by kings. Solemn and secret rituals attended the transforming moment when the image changed from a mere human creation into the god himself.

The temple was the god’s house, staffed by his servants, in which he or she lived a life similar to that of a king. The image was bathed, anointed, and dressed in fine garments and was served food and drink. Sweet-smelling incense was burned in braziers during meals, served in the morning and afternoon. Beer, water, or wine was served in a cup or poured into channels in the altar, while the food, including bread, cakes, fish and meat dishes, and fruit, was set on a table before the deity. Often a curtain was then drawn to allow the god to eat in privacy. After a decent interval, the remains of the god’s repast were removed, to be sent to the king or consumed by priests. On occasion the god might entertain a visiting deity, his servants laying on a special feast.

Records show that huge quantities of food were brought into the temple as regular offerings: some was prepared for the deity, while the rest was fed to the temple staff. To keep the gods pleased with their devotees and happy to reside in their city, hymns were sung in their praise, music was performed, and dramas were enacted that glorified their achievements.

—Jane R. McIntosh

some sites, such as Eridu and Uruk, structures dating from the fifth or fourth millennia onward were periodically reconstructed, enlarged, and embellished, reaching by the third millennium a form that became standard for Mesopotamian shrines. Uruk period temples were often strikingly decorated with mosaic patterns created from clay cones with painted heads embedded in the wall plaster or, in one case, using cones of

white alabaster and red and black limestone. The interior walls of a temple at Uqair bore paintings of people, leopards, and other animals.

The earliest shrine at Eridu was a single room, raised on a platform, with an altar set in a niche opposite the entrance and an offering table before it. The shrine was periodically leveled and reconstructed, becoming increasingly elaborate, with a tripartite plan of central nave and side chambers and with the later addition of further rooms, buttresses, niches, and an increasingly substantial platform with access ramp. In historical times Eridu belonged to Enki, god of the waters; numerous fish bones found on the floor of the shrine—offerings or the remains of ritual meals—suggest that it was dedicated to him from the outset. A similar association is assumed between other prehistoric shrines and the deities historically associated with their city, notably the shrines in the Kullaba and Eanna districts of Uruk with An and Inanna.

The tripartite temple plan continued in the Early Dynastic (ED) period as a large hall flanked by side chambers, with a cella (sanctum) at the far end and its entrance in one of the long sides. Although this bent-axis approach did continue later, most temples from late ED onward had their entrance in the short front wall, often through a monumental gateway with towers. Instead of a hall, a courtyard flanked by rooms often lay between gate and cella, which might be raised, with steps giving access to its interior. This basic temple unit could be multiplied to form a much larger temple complex. For example, the Ishtar-Kititum temple at Nerebtum (Ishchali) contained three temples of different sizes, fitted together to form a rectangle with a massive buttressed outer wall.

Temples were usually built of baked brick, their external walls elaborated with buttresses and niches. The desire for valuable materials to embellish the temple was a major incentive to international trade, as an inscription of Gudea, *ensi* of Girsu, exemplifies. To build a temple to Ningirsu he obtained timber from Meluhha and Magan and copper, gold, silver, and “red stones” (carnelian) from Meluhha. He had trees felled in the Cedar Mountains and Pine Mountains and floated downriver and brought stone from new quarries.

The temple lay within a precinct, often walled, generally in the center of the city. This was the hub of the huge organization that was the temple establishment. It included granaries and storerooms for the products of the temple's lands and industry; offices and archives of records for the administration of the temple and its dependents; the residences of at least some of the full-time temple staff, including the chief priest of the god to whom the precinct was dedicated, and in some cities the *gagum* (“cloister”), a substantial walled enclosure that housed women dedicated to the god's service; sometimes workshops, particularly for the manufacture of textiles; kitchens for the preparation of the god's food; and rooms for the performance of ritual activities, such as ablution to purify officiating priests. In Ur the precinct contained the *giparu*, the palace of the high priestess (*en/entum*) of the city's patron god Nanna, which included the temple of Nanna's spouse Ningal, storerooms, public rooms, and private quarters as well as a crypt where priestesses were buried. Other cities may have had similar establishments within their precincts. As well as the shrine of the principal deity, the precinct generally included smaller temples dedicated to his or her spouse and offspring, with associated buildings.

Mesopotamian Temple Practices

Though the precinct was its central focus, the temple institution also owned substantial lands and buildings outside. These included urban houses for temple personnel and workshops, such as the weaving establishment (North Palace) at Eshnunna. Others lay in the countryside, where the temple might have large industrial complexes, such as the workshop at Guabba outside Lagash staffed by 6,000 workers, and storage facilities, such as those maintained in various villages by the Sin temple at Khafajeh, to store grain grown on temple lands. Although much is known about the major precincts, some smaller neighborhood shrines have also been excavated. These included the Small Temple at Khafajeh and the Single Shrine at Eshnunna. Not all rituals took place in temples; for example, there were rural festivals to which the statue of the god was brought.

The temple combined ritual activities with the practical business of running the god's household and estate. The more important or specialist cultic officials ("priests," although there was no blanket Mesopotamian term with this meaning), administrative staff, scribes, and artisans would have been permanent employees of the temple, as were a number of other essential personnel, such as barbers to shave the priests' heads and cooks to prepare the gods' daily meals.

At their head was the *sanga/shangum* (chief priest), whose role was as much administrative as religious. Others had a more exclusively ritual role, headed by the *en* priest or *en/entum* priestess, who was the spouse of the city deity. This post lapsed after the Old Babylonian (OB) period, although it was revived by the Neo-Babylonian king Nebuchadnezzar II. Other cultic personnel included snake charmers, acrobats, musicians, and singers, and more senior staff included diviners, exorcists, and lamentation priests; the latter may have been homosexuals, transvestites, or eunuchs.

The administrative staff included managers, overseers, surveyors, foremen, scribes and architects, and servants and slaves. Many posts that did not require specialist skills were filled by members of the community who performed regular but limited duties and received rations,

PERSONAL PIETY AND MESOPOTAMIAN WORSHIP

While scholars are well informed about temple and clerical practices in general in Mesopotamia and the role of the king in particular, rather less is known about how private devotions were performed. For example, it is not clear whether ordinary people could enter the cella of the city temple. Smaller neighborhood shrines probably served their needs, and they could participate in processions and festivals. They addressed and made offerings to their own personal god in their domestic shrine and through him might also approach the city deity, a scene shown on numerous seals. When people were in particular need of divine favor, such as when someone was ill, they sought the help of a priest such as a diviner (*baru*) or exorcist (*ashipu*) to perform the appropriate rites and incantations.

Prayers enabled the individual to communicate with the gods. Figurines probably representing an individual or his or her personal god could be set up in the temple. They show the reverent pose adopted by the worshipper, hands clasped against the chest or holding a cup or animal, presumably representing offerings. An extreme form of these perpetual worshippers was the *naditum*, a girl dedicated to the god by her family to keep him mindful of their needs. Children destined for the clergy studied versification, singing, and instrumental music in addition to a normal scribal education, probably in a school attached to the temple. Temples had an orchestra of harps and lyres, wind instruments, and drums and a chorus of singers directed by a lamentation priest (*gala/kalum*) or singer (*nar/naru*). The making of instruments for the temple was important enough to be recorded in date formulae.

—Jane R. McIntosh

wages, or the use of temple land in return. These prebends (as these posts are conventionally known) became the closely guarded privilege of individuals; they were heritable and could be bought and sold. Over the years they frequently became subdivided, and by OB times an individual might be called upon to perform his task as rarely as once a year. Prebendary duties included sweeping the temple courtyard, acting as water carriers or doorkeepers, and baking bread or

brewing beer for the temple. Some ritual duties were performed by prebendary priests known as *gudu/pashishum*.

The temples commanded enormous manpower, in dependents and corvée labor. In Early Dynastic (ED) Girsu, around a third of the city's population of circa 100,000 worked for the temples. Sharecroppers who worked temple lands could be required to undertake corvée labor, receiving daily rations. The temple also maintained many people whom adverse circumstances had made its dependents or slaves: widows, orphans, physically disabled people, and other unfortunates; those who had sold themselves or been sold by their family in payment of debts; children offered as neophytes when their parents could no longer feed them, through destitution or during famine or sieges; and war captives donated to the temple by kings or citizens. Their labor was entirely at the disposal of the temple, which supported them with daily food rations and periodic issues of other necessities or perquisites. These people cultivated temple fields and orchards, tended temple herds and flocks, and worked in temple industries manufacturing textiles and objects of wood, stone, metal, clay, and leather.

Temples often owned substantial estates; for example, around 10 percent of the lands of Girsu in the ED period belonged to the temples. From these, the temple drew enormous revenues in grain and other produce including wool, which was then converted by temple workers into textiles for local use or export by merchants employed or commissioned by the temple. Usury also brought in revenue. The temple made loans at the relatively low rate of 20 percent (the norm being 33.3 percent) to fund private enterprise or buy back prisoners of war or debt slaves and sometimes waived the interest altogether. The temple also entered into business partnerships.

Food and other offerings came both from the community as obligations and from the king and individuals as gifts (*arua*) when divine help was sought or as thank-offerings. *Arua* included land and slaves as well as precious materials and fine objects, often inscribed with the donor's name, and the humbler gifts of private citizens. Many of the everyday objects and materials were issued to the temple staff. For instance, textiles

and wool were among the recorded rations. Gifts of fine clothing, jewelry, and other valuables, however, accumulated in far larger quantities than the god could wear or use. The surplus was stored in what became substantial temple treasuries. A magnet for plunderers when cities were sacked, such treasures have not survived but are known to have existed from detailed inventories kept in temple archives, which list large numbers of metal vessels, fine robes, seals, precious jewelry, drapes for the god's throne, and many other valuable items. Owned by the temple, these nevertheless represented the wealth of the community as a whole, and their loss in war would have had devastating economic consequences.

Mesopotamian Festivals— The New Year's Celebration

The Mesopotamian religious calendar was filled with festivals and events where the human and divine communities mingled. Mesopotamian gods paid each other formal visits in the person of their statues, often traveling by water in a sacred boat. In third-millennium Sumer and Ak-

kad, city gods visited their mentor Enki in Eridu and their leader Enlil in Nippur and also engaged in more local visits between deities of similar status. The occasion of these visits might be a festival in which the deity wished to participate or an important event such as the consecration of a major temple. In addition, a god's statue, or more commonly his emblem, often traveled locally to support situations where an oath was to be taken or divine authority required, such as in a lawsuit or for official validation of the size of a harvest. Major public enterprises such as temple construction were attended by rituals at every stage, beginning with the king molding the first brick or carrying the first basket of soil, a theme frequently appearing in dedicatory art. Public rituals were performed to protect the king or the state, for example, to safeguard the army when it went to war. The investiture of a new king was a solemn religious occasion during which his symbols of office—crown, scepter, and throne (actually hat, rod, and stool)—were presented to him in the temple and sacrifices were made.

The Babylonians' most important religious celebration, the Akitu festival, was celebrated in Babylon at the New Year, from the 1st to the 12th days of the first month, Nisannu (March/April). Only the 2nd to 5th days are well known, from surviving fragments of a detailed Neo-Babylonian text. Although *akitu* in Babylon was the New Year festival, the term was widely used in earlier times for a variety of rural festivals, not necessarily associated with the New Year. Though little is known of festivals other than the Babylonian akitu, they probably generally included processions, music and dancing, feasting, and other communal activities. People probably traveled from a wide area to attend festivals. Individual deities had their own special festival days, and smaller-scale celebrations were widely held for the phases of the moon, on the 1st, 7th, and 15th days of each month.

The main purpose of the Babylonian akitu festival was to inaugurate the New Year, when the gods not only began the annual cycle anew but also re-created the world. For this reason, a complete reading of *Enuma Elish* (the Babylonian creation account) had become an integral part of the ceremonies in Babylon by the first millennium. The New Year also coincided with

➤ THE SACRED MARRIAGE CEREMONY

The sacred marriage was a major festival about which, unfortunately, tantalizingly little is known. Probably originating in Uruk, the city of Inanna, the goddess of love, and celebrated by the Ur III kings and early-second-millennium kings of Isin, it may have been more widespread, possibly elsewhere involving a marriage between the king and a different deity. The entum priestess at Ur was regarded as the bride of the city's god Nanna, and there are indications that a sacred marriage formed part of the New Year festival here, presumably with the king enacting the part of Nanna and the entum representing his wife, Ningal. A bedroom in the shrine in her residence, the *giparu*, was probably intended for this celebration. Accounts of the ceremony make it impossible to say whether the ritual was purely symbolic, the king spending a night in the goddess's chamber in her spiritual presence, or entailed the actual physical union between the king, representing Inanna's husband Dumuzi, and the goddess, personified by a priestess. Nor is it known whether this took place annually as part of the New Year festival or more infrequently, for example, at the first New Year after the king's accession.

—Jane R. McIntosh

the time of the barley harvest in Babylonia, the high point of the agricultural year. Marduk, as chief of the gods in later Babylonia, creator of the universe according to *Enuma Elish* and city deity of Babylon, played the central role in the festival.

It opened with purification ceremonies, and rituals began in earnest on the second day. One priest known as *sheshgallu* rose early each morning, washing in river water and offering prayers before the statue of Marduk before opening the doors of the shrine to admit other priests, who performed a number of rituals. On the fourth day the curtains were drawn back from the images of Marduk and his wife, and the Esagila was blessed. Later in the day the sheshgallu recited the whole of *Enuma Elish*.

On the fifth day an exorcist purified Marduk's shrine by sprinkling it with water. The shrine of Marduk's son Nabu, patron of the nearby city of

Borsippa, was also purified, ready for his arrival in the person of his statue. The shrine was wiped ritually clean with the body of a sacrificed sheep, which was then thrown in the river, carrying away any evil. In Marduk's temple prayers were said, and he and his wife were served a meal. Now came one of the high points of the festival, when the king answered to Marduk for his year's care of Babylonia. Everyone left the cella (the central area of the shrine) except the sheshgallu and the king. The priest removed the king's regalia—scepter, circle, and sword—and placed them before Marduk. He then slapped the king's face and dragged him by the ear before Marduk, forcing him to bow. The king assured the god of his righteousness in avoiding sin and fulfilling his duties throughout the year; he “took Bel [i.e., Marduk] by the hand,” and the priest restored the regalia to him. He then slapped the king again hard. If tears came to the king's eyes, this signified that Marduk was pleased and well disposed. At sunset of the fifth day, a trench was dug in the courtyard outside Marduk's sanctum. Into it were poured oil, honey, and cream along with reeds. The king set this alight and sacrificed a white bull, reciting prayers along with a priest.

What happened during the rest of the festival is not well known. One of the ceremonies involved breaking and burning two divine images made earlier in the festival from valuable wood covered by sheets of precious metal. Statues of Marduk and his divine court were brought together to discuss the fate of the king and the Babylonians, with Nabu recording their decisions. The climax was a great procession that carried these statues in palanquins along the magnificent Processional Way paved with limestone slabs, its walls and the magnificent Ishtar Gate decorated with glazed bricks, blue for the background contrasting with orange low-relief figures of the dragon of Marduk (*mushbusshu*) and the bull of Adad on the gate and lions on the wall. This road led from Esagila through the Ishtar Gate to the Akitu temple outside the inner city wall. The procession, which may have taken more than a day to complete, had seven stages, including each god crossing the Euphrates in his own boat. At the Akitu temple, Marduk was installed in the central shrine, and it is likely that

a ceremony took place commemorating and perhaps reenacting Marduk's great victory over Tiamat.

Where Did the Harappans Worship?

As compared to the great ancient river civilizations of Egypt and Mesopotamia, one feature that stands out when examining the archaeological evidence from the Harappan or Indus civilization is the lack of monumental architecture, especially structures with clear religious functions. In other words, no clear evidence has emerged from ongoing excavations that religious structures such as temples, which abound in modern India, were part of the religious or political landscape of the Indus civilization. However, although there are no temples, some architectural structures from Mohenjo-daro, which along with Harappa is one of the two most significant urban centers, inform us about where the Indus people may have worshipped. From the Great Bath and the College of Priest, both of which are located on the Great Mound at Mohenjo-daro, we have been able to draw some conclusions about the nature of communal worship in the Indus civilization.

The Great Bath and the College of Priests are located in the Mound of the Great Bath, an area set aside and elevated from the Lower Town. The structure of the Mound area indicates that its planners carefully considered the symbolic func-

tion and effect of architecture, since the Mound's elevation effect on a resident of the Lower Town would be to stress the areas' separateness, exclusivity, and dominance. The structures housed in the Mound also shared the symbolic effect of the Mound's elevation. The Mound of the Great Bath stands as a unique structure in the Indus Valley, as there are no other similar mound structures in any other sites except at Kalibanga, which has a separate High Mound but lacks a Great Bath or other related structures.

The most religiously significant structure found in the Mound is the Great Bath. It consists of an open quadrangle with verandas on each of its four sides. On three sides, there are galleries and rooms. There is a series of seven, possibly eight, chambers along the eastern side of the Great Bath. At the center of the open quadrangle there is a large swimming-bath (approximately $39 \times 23 \times 8$ feet). There are two sets of stairs at opposite ends of the swimming-bath leading down into the bath. These stairs are reminiscent of the steps leading to the *ghats* along rivers such as the Ganges and Yamuna. At the time that Mohenjo-daro was occupied, the Great Bath was fully functional. The archaeological evidence suggests that the bath was filled with water. The chambers along the east side of the bath seemed to have functioned as bathing rooms. The universal function and significance of water as both physically cleansing and symbolically purifying is strongly intimated by this structure. Because of its location in the Mound, access to the Great Bath is unlikely to have been universal but rather was limited to individuals within this society who were permitted to use the Great Bath for particular religious rituals.

The College of Priests, excavated by Ernest J. H. MacKay (1888–1943), is a very large building, approximately 230×78 feet (70.3×23.9 meters), located across the street from the Great Bath. The principle entrance to the college seems to have been located along the western wall, facing the Great Bath. Some of the spaces within the college follow the same pattern as that of the northern wall of the Great Bath. Due to its proximity to the Great Bath, the college probably functioned as a building by religious specialist or residential facility for persons who were permitted access to the Great Bath.

Other large houses in Mohenjo-daro that do not fit the general pattern and character of domestic buildings have been excavated, but there is no convincing evidence to indicate that they were used as temples or had any other religious function.

Besides these two structures, there is hardly any evidence of monumental architecture in Mohenjo-daro or in other part of the Indus civilization. No clear examples of structure with a religious function, such as temples, have been found. From the lack of such architecture, archaeologists agree that the primary expression of worship in the Indus civilization was an individual or family obligation.

Changes in Chinese Ritual Practice during 4000–1000 BCE

The vast area known as China experienced great cultural diversity during the late Neolithic and Early Bronze Age. Attempts at grasping this diversity in general terms would not do justice to it, nor would it be possible. However, some regions in northern and eastern China have been better researched than others, thereby offering valuable case studies on ritual practice for the period toward the end of the Neolithic (ca. 4000–2000 BCE). Even better evidence for ritual exists for the Early Bronze Age (ca. 2000–1000 BCE), which saw the advent of the first historical dynasties in China.

Unlike the Mediterranean world, where temples were made of durable materials such as stone, monuments of this kind are notably absent from the Chinese archaeological record. Most buildings were made of ephemeral wood on earthen platforms, and the exact function of

► BRONZE RITUAL VESSELS FROM A TOMB AT ANYANG

A set of bronze ritual vessels was unearthed from the late Shang period (ca. 1250–1050 BCE) tomb no. 18 at Anyang, Henan Province. These vessels were the typical funeral trappings of a lesser member of the Shang elite. Their presence in the tomb illustrates the emphasis on wine over food vessels, which is characteristic of the ritual vessel assemblages of this period. It is not clear if this reflects the importance of wine in Shang ritual or a more generalized importance of wine in Shang society.

—Sascha Priewe

these remains open for debate. Thus, the overwhelming evidence for ritual and religious activities comes from excavated cemeteries. One notable exception to the use of ephemeral materials is the complex at Niheliang, near Chifeng city in Inner Mongolia, that consists of a group of cairns and a semisubterranean structure that may have been a temple, all dated to circa 3500 BCE. The cairns were furnished with large amounts of jade objects in the shape of turtles, birds, tubes, and coiled creatures identified as dragons. Jade has always been a conspicuous medium in China due to its durability and translucency. Its appearance in Neolithic tombs may not only mark the deceased's status but may also have some ritual significance. The structure is a cross-shaped pit building from which sculpted clay in the form of a pregnant female and a face with inset jade eyes were recovered. These finds were linked to a fertility cult, but we cannot be sure what activities were actually carried out since the building was only partially excavated. However, we can reasonably conclude that some sort of ritual was played out in this landscape.

A comparison between two regions of Neolithic China illustrates the different forms of ritual activities prevailing during this period. The first example is the Dawenkou culture (ca. 4200–2500 BCE) in Shandong Province on the east coast. Evidence from cemeteries reveals that the pottery buried with the deceased included tall-stemmed goblets, known as *gu*, and high-

stemmed food serving dishes, known as *dou*. This shows that the consumption of beverages, possibly alcohol, and of food may have been central to the funerary rites of this region. By contrast, the funerary rites as mirrored in the grave goods of the Machang phase of Majiayao culture (ca. 2300–2000 BCE), along the upper reaches of the Yellow River in China's northwest, show a different emphasis. Most tombs contained large numbers of a type of globular jar with a lavishly painted upper half. These jars may have been used for storing grains, although the jars buried with the deceased may have only been a symbol of this function and were not actually used in this way. This suggests that rituals emphasizing the communal accumulation of goods in the case of the death of a community member were in place. This comparison illustrates the diversity of ritual during the late Neolithic and particularly the different ways in which societies took care of their deceased.

The use of goblets made of eggshell-thin pottery and associated ritual practices continued into the following period, known as Longshan culture (2500–2000 BCE). Roughly contemporary with this period is the so-called Liangzhu culture (ca. 3300–2200 BCE) in the Lower Yangzi Delta. Its burials illustrate the entirely different nature of ritual in this region. Here, large man-made mounds constitute what is considered to be the burial grounds of the elite. The tombs on these mounds were furnished with large numbers of jades, such as disks with a circular central hole, called *bi*, and square tubes with a circular cross section, called *cong*. Although we cannot know the exact function or meaning of these objects, there is a high probability that these were used in rituals. Many scholars have inconclusively argued that these jades were used in the communication between heaven and earth, and some have even gone so far as to say that they were employed in shamanist activities. However, the exact nature of these practices remains elusive; notably, the question of shamanism as part of religion in late Neolithic and Bronze Age China remains unresolved. What is definite is that during the Neolithic, people cared for their dead in a very thoughtful and orderly fashion in relation to philosophical and religious beliefs.

The worshipping of ancestors was a central concern in Bronze Age religion, and some aspects of ancestral cults may have already been in place during the Neolithic. From circa 1800 BCE onward, when bronze vessels were cast for use in ancestral rituals, ritual practice in North-Central China was transformed dramatically. The first vessels were found in tombs at the Erlitou site in Henan Province. Architectural foundations, such as that of a courtyard with a central building on a pounded-earth platform, were also unearthed at Erlitou. Although the function of this complex is unclear, it can be estimated that if used for religious activities, it would have been big enough to accommodate a large audience.

During the following Erligang phase (ca. 1600–1300 BCE), commonly regarded as the early stage of the Shang dynasty, the bronze vessel repertoire became more varied. The finest vessels come from three pits believed to be sacrificial deposits at Zhengzhou, Henan Province. They all contained *fangding*, or large square food vessels on four feet, as well as a number of wine vessels. Assuming that these vessels were used together in offerings to the ancestors, it is important to note that both food and wine vessels are found in approximately similar numbers. Unlike the later Anyang period (ca. 1250–1050 BCE), the ritual did not primarily involve the consumption of alcohol. This impression derived from the bronze vessel assemblages found in tombs dated to the end of the Shang dynasty. The majority of vessels were goblets, pouring vessels, and containers for wine. At Anyang we may also have evidence for an actual ritual site, since a small building was found to have stood on top of the tomb of Fu Hao (Lady Hao, d. ca. 1200 BCE), a consort of King Wu Ding, of what may have been a shrine to worship her memory. Additional evidence for late Shang ritual comes from the many pits containing human and animal sacrifices that accompanied the burials of high-ranking members of Shang society. Although human and animal sacrifice also occasionally occurred during the Neolithic, the Shang nobles realized them on a hitherto unprecedented scale.

Just as important as the bronze vessels—which were not only used in life for offerings to the ancestors but were also buried in tombs for the occupants to continue this practice in the

afterlife—is the divination practice associated with so-called oracle bones. There is evidence that the shoulder blades of oxen and the shells of turtles had been used for foretelling the future since circa 3500 BCE. The bones were deliberately cracked by applying heat to them. The cracks were then read by ritual specialists. Only by circa 1250 BCE do we know of the precise nature of the divination, since oracle bones began to be inscribed with the questions asked to the ancestors and the answers given as result of the interpretation of the cracks. This form of divination was employed to investigate the success of the king in a number of matters such as military endeavors, the health of the king and his consort, and also the weather and agriculture. Thus, in using both bronze vessels and oracle bone divination, the Shang rulers attempted to secure the benevolence of their ancestors for the benefit of the state.

Only during the Early Bronze Age can we speak of ritual forms reasonably identifiable on the basis of the oracle bone inscriptions and increasingly also inscriptions on bronze vessels. The wide distribution of very similar bronze vessels across parts of North and central China during the Erligang period suggests that similar religious practices were in effect across a large territory, although this may have only affected major centers. This appears to have changed during the Anyang period when local cultures, for example, along the Yangzi River in southern China created their own very distinct bronze vessels. This suggests that very different ritual practices were carried out in these southern regions at this time. It appears that at no time during 4000–1000 BCE can we speak of ritual unity in China, as there does appear to be great regional diversity.

Shang Religious Practices—Burial Pits, Human Sacrifice, and Ancestor Veneration

Sacrifices of humans, animals, and objects were important components of the Shang belief system. Archaeologists find the remains of sacrificial ceremonies preserved in pits; the burying of the sacrificial victim seems to have been the final step in the ritual. Roasting meat and sweet millet wine were, it was thought, pleasing to the various deities worshipped by the Shang. Dismemberment of animals and humans was similarly important. Human sacrifice seems to have been an important part of the veneration of Shang kings, both living and dead.

More than 2,000 of these sacrificial pits have been identified at the late Shang capital of Anyang (ancient Yin) alone. Most of these pits are oriented north to south and are rectangular in shape. There is not much consistency about what is contained in the pits. Sometimes they are full of skeletons, sometimes only heads, and some-

times headless torsos, and they often contain more than one person. Animals and objects are frequently included in the burial pits as well. Who these sacrificial victims were is not entirely clear. They were probably a combination of people captured in battle and offered by subservient villages or regions as tribute, but this is far from certain. Regardless of the theological justifications, the fact that a king or religious functionary could demand a human sacrifice marks a substantial degree of power.

David Keightley has argued that it is possible to discern social ranking among the sacrificial victims interred directly in tombs, especially at the cemetery of Xibeigang. Guardians were buried with weapons, their bodies intact close to the bottom of the tomb so as to protect the deceased. Dogs were also buried in this level, possibly also for protection. Some were buried with bodies intact in their own coffins; they were probably relatives or servants of the deceased. Young decapitated males were buried in the earthen fill of the tombs; given the violent nature of their execution and the lack of care given in the treatment of their remains, these may have been enemies captured in battle.

A few Shang rituals, known from textual sources (mostly offhand references in divination texts), involved the veneration by the Shang king of his ancestors. The *bin* ritual and the *xiang* ritual (both of which are not well understood for this period) involved some kind of interaction with the ancestors. Divination texts also record a five-ritual cycle in this type of veneration. The people of the Shang culture believed that departed ancestors still played a role in the living world and that one's social ranking remained relatively constant after death. It was of vital importance that rituals surrounding funerals were performed accurately in order to facilitate the transformation of the deceased into a living ancestor.

Royal ancestor veneration was thus more elaborate since these ancestors were still perceived as holding power in the earthly realm. In fact it was the king's relationship to these deceased ancestors that legitimized his authority on earth. Each royal ancestor was given a spirit tablet, which was kept in a temple. Some individual kings and royal consorts had temples created

► THE SACRIFICIAL PITS AT SANXINGDUI

One of the most spectacular finds in Chinese archaeology is of a sacrificial burial pit, contemporaneous with the Shang dynasty but outside of the Shang sphere of influence, at Sanxingdui in Sichuan. Two great pits had been dug in antiquity and filled with animals and ritual objects. The contents were set afire and, after burning, were buried. Archaeologists have unearthed more than 700 artifacts from the two pits along with the carbonized remains of the animal sacrifices. Objects of gold, bronze, and jade were preserved. Forty bronze human heads and masks were found; these were not realistic human images but highly stylized figures. Cowrie shells and tusks were also included in the ritual burning and burial.

—Kevin M. McGeough

specifically for their veneration; these temples were maintained long after the death of the venerated ruler.

■ Introduction: Diviners, Shamans, and Other Specialists of the Unseen World

Those who understood the will of the gods and knew how to communicate with them, those who knew how to harness some of the powers typically reserved for deities, and those who claimed to fully understand the unseen or supernatural world were among the most influential individuals in the societies of the ancient world. These people could exert influence over the king, advising him on particular courses of action. These people also ran the risk of seeming too dangerous to their community, given the kinds of sentences given to those found guilty of practicing witchcraft according to the legal records of ancient Mesopotamia. It can be difficult to differentiate science and magic in the ancient world, especially since these were not conceptually separate areas of study in antiquity. Medicine and the interpretation of dreams certainly could be considered as either.

Of these arcane types of knowledge, the most rigorous was divination. Not really fortune-telling in the way that we think of it today, diviners attempted to communicate with the gods or attempted to understand signs that the gods had sent to the earth as messages. Astrology and hepatoscopy (the study of entrails, usually the livers, of animals) were the most common and the most rigorous in the ancient Near East. In China, tortoise shells were the medium of choice for these kinds of practices. These were scientific, in one sense of the term, in that they were based on empirical observations: correlations of

various phenomena with sociopolitical events. Divination was incredibly complex and sophisticated, requiring years of training and practice. These practices were taken quite seriously, and in fact writing may have been invented in China for this purpose. These practices were especially important in planning military strategy; a good or a bad omen could help a king decide when to go on a military campaign. In some cases, magicians were part of the military strategy.

—Kevin M. McGeough

Hepatoscopy

Hepatoscopy (from a Greek term meaning "inspection of the liver") is the practice of examining the liver of a sacrificial animal, usually a goat or sheep, to look for encoded communications from the gods. Although hepatoscopy developed independently as a divination technique in several world cultures, it is first attested in cuneiform sources from ancient Mesopotamia in the third millennium BCE. In fact, hepatoscopy was among the most important techniques of Mesopotamian omen science, the evidence for which has come down to the present through cuneiform clay tablets written in the Sumerian and Akkadian languages. The most common animal used for hepatoscopy was a sheep or lamb, although goats and birds were also sometimes used. In this context, ancient peoples believed that a divine message appeared in the condition

► LIVER MODELS

Beginning in the third millennium BCE, diviners in Mesopotamia manufactured models of the sacrificial animal's organs. These models are readily identifiable today because of their anatomical precision and realism. Liver models are the most common, but the lungs, spleen, and intestines were also represented. Such models have been discovered throughout Mesopotamia, the Levant, Cyprus, and Anatolia in houses, palaces, and temples. The primary material that the diviners used for these models was clay, although a few ivory models are also known from the thirteenth-century Ugarit on the Syrian coast. By the late first millennium the practice of manufacturing liver models had spread to Italy, where an Etruscan bronze liver model was found.

The earliest known piece is a model spleen from mid-third millennium Mari on the Euphrates. By the early second millennium BCE diviners in southern Mesopotamia, the Diyala River basin, and at Mari began to inscribe some liver models with cuneiform texts in the Akkadian language. Later models also used the Hittite or Ugaritic languages native to Anatolia and Syria. The production of inscribed liver and lung models continued in first-millennium Mesopotamia.

The models appear to fit into the two broad categories of hepatoscopy: reports and compendia. The difference from the other sources is that liver models physically represent the marks and abnormalities that texts can only describe. Some

Clay model of a liver for divination, early second millennium BCE. (Erich Lessing/Art Resource, NY)

models appear to represent a single act of hepatoscopy and are therefore like the written reports. Others appear to have been used for educational purposes. These models would teach the diviner the appearance and interpretation of various possible configurations of the liver, reinforcing what he learned from copying omen collections.

—Matthew T. Rutz

of the animal's liver: its shape, color, and general anatomy. The arrangement of these anatomical features was thought to come as the answer to a specific question about one of the many universal anxieties of the human condition. Personal, political, military, economic, and religious affairs are all prominent in the hepatoscopy literature. More general terms used by modern scholars to refer to hepatoscopy are "extispicy" and "haruspicy" (both meaning "inspection of the internal organs"), which derive from the Latin vocabulary used much later by the ancient Romans to describe similar divination methods.

The earliest historical evidence comes from the mid-third millennium BCE. King Ur-Nanshe of Lagash (ca. 2500 BCE) reports that he chose a

high religious functionary by means of hepatoscopy (literally "chosen by means of a goat"), a practice that continued into the early second millennium BCE. In the mid-third millennium there were also lists of various professional titles, among which were the titles used by the practitioners of hepatoscopy, the diviners. The diviner bore the title "he who extends (his) hand (into) the goat" or simply "he of the goat." In the second millennium another common word for the diviner was "seer." Calling a diviner a seer did not mean that he was a clairvoyant or medium. "Seer" was simply a shorthand description of the diviner's ability to examine and interpret an animal's internal organs. This craft was no innate, psychic ability: there is evidence that diviners

undertook many years of education and apprenticeship to train for a career as a diviner. Once established, the diviner frequently went out on military campaigns to ensure divine approval of the king's attack strategy or peace negotiations. Because of these political and military involvements, there is good reason to believe that diviners functioned in part as diplomats, spies, and military consultants. Because of their enmeshment in international and court intrigue, diviners were made to swear oaths of loyalty to the kings who employed them. Much of our knowledge about diviners comes from letters between kings and their diviners.

There are four important types of sources for the practice of hepatoscopy in the second millennium BCE: rituals, reports, omen collections, and models. The diviner's ritual was a complex affair. First, he had to purify himself using cedar and tamarisk. The animal that was to be sacrificed had to be pure, unshorn, and without blemish. The animal, usually a sheep or goat, was referred to as an offering. The diviner posed a question on behalf of his client, whispering the question in the ear of the sacrificial animal. The diviner then requested that the gods write favorable signs on the animal's entrails, which in some texts are referred to as the (cuneiform) tablet on which the gods wrote their answer. The animal was dedicated to both Shamash, the sun god, and Adad, the storm god, and then slaughtered. Some of what the diviner said was fixed in writing. He typically addressed the sun god in his role as lord of justice as well as the storm god, who was the lord of hepatoscopy. The materials and symbolism of this exchange are derived from Mesopotamian legal tradition. The diviner then recited a prayer in which he requested the specific configuration of the animal's internal organs that he hoped to see. The diviner interpreted and sometimes recorded the results of the examination in a hepatoscopy report.

In the second millennium BCE diviners in Mesopotamia would occasionally write short reports of the results from the examination of a specific animal's organs. Many of these texts are dated to the reign of a particular king. The reports contained a basic physical description of certain aspects of the entrails: the position, condition, and features of the liver, gall bladder, lungs,

stomach, and intestines. Some reports were included in letters, but the most detailed texts contained only the description of the procedure's results. Using his specialized training in anatomy and interpretation, the diviner would tally up the total number of positive and negative marks on the various organs. If there were more positive marks than negative portents, the overall outcome of the inquiry was positive and vice versa. Results of a report were only valid for a particular period of time. Because it was necessary to repeat the procedure over time, hepatoscopy was big business. One record notes the numbers of sheep required for hepatoscopy each month, typically between 300 and 700. In a few instances a report contained brief mention of the reason for the query: the prospects of a new business venture, the likelihood that a god will cease to be angry (probably a euphemism for illness or other misfortune), or the meaning of a recurring dream. The report texts are particularly important for the history of hepatoscopy because they sometimes contain the name of the person for whom they were produced. Reports are thus one realm where we see figures other than the king using hepatoscopy to shape their lives. The hepatoscopy reports also give some hints as to how diviners earned their daily income.

The collections of hepatoscopy omens are often called compendia. The first systematic records of hepatoscopy date from the eighteenth century BCE. The omen tradition was already highly structured by this point, which has led scholars to believe that the first organization of the material came much earlier. If it existed, this earlier stage is not preserved in the archaeological record we have before us. Hepatoscopy tablets were probably copied as educational tools for apprentice diviners and as reference works for the practice of divination. By the latter half of the second millennium these collections were found throughout Mesopotamia, southwestern Iran, Syria, and Anatolia. These hepatoscopy omen collections later became long, elaborate treatises attested in the first millennium. Near the end of the second millennium, some unknown diviners brought together a variety of different texts and created an ancient composition called the seer's craft. This work consisted

of thousands of omens collected in about 100 sections, or tablets, that in turn were organized into ten chapters. In all periods these texts list omens that correlate the state of some aspect of the liver or entrails with a particular event in the world. The liver omens follow the basic “If A, then B” pattern common to all facets of Mesopotamian omen science. For example, an early second-millennium liver omen recounts the meaning of the appearance of “Weapon marks” on different areas of the part of the liver called the “View”:

“If at the top of the View there are two Weapon marks on the right and left facing each other: some king will write to you about a peace settlement; you will accept his peace settlement; in a revolt you will keep away from his cattle.

“If in the middle of the View there are two Weapon marks on the right and left facing each other: undecided result.

“If at the base of the View there are two Weapon marks on right and left facing each other: you will write to some king about a peace settlement; you will accept his peace settlement; in a revolt he will keep away from your cattle.”

Most of the results (“then B”) of these omens bear some relation to the fate of the king and the land: the death of the king or someone in his family; plots against the king; uprisings in the land; a long, enduring reign and victory in battle against some enemy; natural catastrophes; or a bountiful harvest. Sometimes the omens are even cast in the first-person “my troops” as opposed to “the king’s troops,” even though we have no reason to believe that the king himself actually authored any of these texts.

Mesopotamian Omen Science

Mesopotamian omen science was not science as it is understood today. Though based on empirical observations about the natural world, Mesopotamian omen science blurred the boundaries between what we know as science and religion, which did not exist as separate categories in Mesopotamian thought. Rather, omen science was a specific kind of knowledge derived from detailed observations of the natural world. Specifically, this knowledge was concerned with looking for and reading signs encoded by the gods in the fabric of everyday life. These empirical observations were then coupled with a belief that the correct interpretation of the signs could predict seemingly unrelated events. Using the

cuneiform writing system, ancient diviners wrote down these observations and predictions on clay tablets. The format of these omen collections was “If A: then B.” The proposition made in the statement “If A” is called the protasis. The result, “then B,” is called the apodosis. This formulation of cause and effect is common to omens, Mesopotamian medical texts used for diagnosis and prognosis, and Mesopotamian law collections, such as the famous Code of Hammurabi. Sometimes modern scholars can discern what connects A and B in a particular omen. More often than not, the ancient thought process behind the association is completely obscure. The schematic nature in which Mesopotamian omens were written was also the basis for theoretical elaboration. As written, omen traditions developed in the second and first millennia BCE, and there was an increasing tendency to move beyond what was strictly observable in the natural world. The result of this creative process was that the omen collections sometimes came to treat physically impossible or improbable cases.

Diviners looked for divine signs almost everywhere. Some of the earliest collections of omens are from the realm of hepatoscopy, the examination of an animal’s entrails. Other omens were taken from the casting of oil onto water or water onto oil and then observing the visual effects such as color or brightness. Still other omens were drawn from the behavior of smoke from incense sprinkled on a censer. For example,

“If when you sprinkle incense (on the censer) the glow varies in intensity: Your army will defeat an enemy.

If when you sprinkle incense (on the censer) the coals consume it, and afterwards the glow varies in intensity: An enemy will defeat your army.”

The next lines in the same text deal with the right-left symbolism that occurs throughout Mesopotamian omen literature, where the right is positive and the left negative.

“If when you sprinkle the incense (on the censer), (the smoke) goes to its right and does not go to its left: You will prevail over your adversary.

If when you sprinkle the incense (on the censer), (the smoke) goes to its left and does not go to its right: Your adversary will prevail over you.”

These omens are what modern scholars call provoked omens, since the diviner does something, provoking the gods to respond, and then observes and interprets the signs.

Other omens were unprovoked. Celestial omens were derived from observing the sky by night and day. Omen traditions were also constructed around good and bad days of the calendar year for performing certain activities, such as building a house or eating a particular food. Still other omens were derived from the human world, for example,

“If a city is set on a high place: Living in that city will not be good.”

In these cases the diviner simply observed the world around him. Unusual natural occurrences must have particularly grabbed diviners’ imaginations. For example, teratology, the study of abnormalities in babies at birth, provided one source for signs:

“If an abnormal birth is like a wolf: There will be a plague in the land.

If an abnormal birth is like a brick: Hard times will seize the land, and the value of the standard measure will fall.

...

If an abnormal birth has no bladder: The torrent in the river will be stopped; rain in the sky will be scarce.

If an abnormal birth has the face of a lion: There will be a harsh king, and he will weaken that land.

If an abnormal birth has the face of a bird that is an evil omen: That land will experience famine; its enemy will prevail over it.

...

If an anomaly has no tongue: The reign will be the reign of a wicked person; liars will rise up and destroy the land.”

There were relationships among various types of divination. As in ancient Rome in the

first millennium BCE, these omens show that Babylonian diviners sometimes observed the behavior of birds as ominous events. Other omens could be derived from animal or human behaviors, such as the behavior of a sheep just before it was to be sacrificed. Human behaviors and appearance were also sources for signs. For example,

“If a man’s clothes keep falling off: There will be confusion.

If a man looks at another man he knows and does not recognize him: That man is entrusted to the hands of death.

If a man winks with his right eye when he looks at something: He will experience hardship.

If a man winks with his left eye when he looks at something: He will experience righteousness.

If a man blinks with both of his eyes: His head has been struck, and just as his head has been struck, so also his mind will be struck.

If a man’s hair is red like dyed wool: That man will never have peace of mind.”

Dreams were an obvious source for omens. Necromancy, asking questions of the dead, is only very rarely attested in ancient Mesopotamia.

Divination and diviners are described in Sumerian texts from the third and early second millennia BCE. However, it is significant that almost no omens are known to have been written in Sumerian, and those that have been identified appear to be later translations from Akkadian. Observations of the natural world were written down in Akkadian and compiled for the first time to form extensive divination handbooks in the early second millennium. The vast majority of this literature was written in Akkadian, which continued to be the primary language of omen science throughout the first millennium BCE as well. In some regions outside of Mesopotamia omens were composed in or translated into local languages. Many Hittite and Hurrian omen collections are known from Anatolia and Syria. A few collections of omens were written in alphabetic Ugaritic in Syria, and Elamite omens have been discovered in present-day Iran. In the first

millennium BCE a magical system was developed to try to avert the dangers foretold by bad omens.

Shang Oracle Bones

At the turn of the twentieth century, scholars noticed that some so-called dragon bones were inscribed with ancient writing and other marks consistent with traditional accounts of divination practices from the Shang era. Rather than grinding these bones for medicinal purposes, growing numbers of scholars and scavengers searched for the source of these bones, which led to a series of important discoveries beyond these records of divination and the earliest form of Chinese writing. Subsequent excavations near Anyang have unearthed approximately 200,000 oracle bone fragments from the late Shang, twelfth, and early eleventh centuries BCE. The modern discovery of these bones excited great interest because they provided archaeological evidence both of early divination practices and of the historicity of the second millennium BCE Shang Dynasty, whose kings reigned from around the eighteenth or seventeenth centuries to the eleventh century BCE. Prior to the discovery of these bones, the oldest written records in China came from the Zhou (Chou) dynasty, which became powerful in the eleventh century BCE. Now the Shang is earliest of the traditional eras with written records to unambiguously verify its historicity. Furthermore, analysis of the oracle bones provide insights into Shang practices and concerns without the filter of Zhou historians, who justified their dynasty's rule by recounting how virtuous Zhou rulers displaced dissolute Shang kings. The Shang may yield this status of earliest verifiable dynasty to the Xia (Hsia) if ancient sites, such as Erlitou, can be more definitively associated with Xia rather than Shang culture; however, traditional notions of sequential succession from Xia to Shang to Zhou have given way to models of overlapping eras.

In addition to advancing the understanding of early dynastic history and culture, the oracle bones are particularly instructive for understanding divination practices in ancient China. Shoulder blades (scapulae), taken from cattle and related large animals, along with the underside portions of turtles' shells (plastrons) were especially popular for divination, as each provided a broad, flat surface. Shang-era diviners made partial holes in the reverse side of oracle bones, ap-

Shang dynasty oracle bone, Henan, China, second millennium BCE. The bones were used for divination, but provide historians with information about rulers, battles, folk religion and religious rites. (Lowell Georgia/Corbis)

plied heat (some type of fiery poker), observed the resulting cracks, and then wrote out the charge, or proposition, as a record of the divination. In fact, this early form of divination is synonymous with crack making, and the corresponding Chinese character signifying divination, *pu* (卜), retraces the most common crack form, which was guided by the hollows bored into the reverse side of the oracle bones. Although it is not entirely clear how the cracks were read, many of the bones include writing that announces the subject of the divination, such as a proposition concerning crops, health, royal excursions, alliances, childbirth, weather, or warfare. Some oracle bones even include notes of how the Shang kings had interpreted the divination, and a very few report the outcome.

These charges inscribed onto oracle bones were often asked in both the negative and affirmative to more conclusively determine whether a sacrificial offering had been received satisfactorily, whether a planned sacrifice was appropriate in terms of the offering and recipient, what had gone wrong in the past, or what prognostication could be discerned about the future well-being of crops, kings, and their kingdoms. Although often discussed as questions directed to gods, spirits, and ancestors, most charges are in the form of statements, which might be seeking favor more than a mere forecast. For example, "If millet is planted in ten days, the outcome will

➤ SACRIFICE AND DIVINATION

Shang oracle bones provide evidence of how sacrifice and divination worked together in ancient times much as they do in Chinese religion today. Sacrifice and divination were complementary practices in the reciprocal relationship between humans and gods. Sacrifice involves carefully orchestrated rituals of providing offerings to ancestors and other spirits and gods. While animal sacrifice was most common, written and archaeological records confirm that Shang rulers offered human sacrifices as well. Whatever the offering and to whomever it was directed, there was typically an expectation of obtaining certain practical benefits in return. Divination helps both to confirm the acceptability of a sacrifice and to discern, or perhaps even influence, the will or plans of gods and spirits whose favor and intervention may have been solicited or whose wrath may have been propitiated through sacrifice improperly performed.

—John Harding

be favorable.” “There will be rain.” “There will not be rain.” “We should offer to Father Xin three sheep.” “An alliance with such and such a kingdom will lead to benefit.” “Shang Di might not offer assistance if the king should join Zhi Guo in an alliance.” “There will be no misfortune this evening,” or “there will be no misfortune this ten-day ritual week.” “It is an auspicious time for a battle,” or “it is an auspicious time for a hunt.” “The king’s illness is due to Father Geng cursing him.” This last statement is representative of a category whereby some disaster has happened already and divination is used to determine whether the misfortune is due to an ancestor, such as this deified former king, or a ritual mistake. Divining the cause of misfortune helped to determine and direct subsequent sacrifices and divination.

While much of the later divination in Chinese religion relates to more abstract concepts of chance or cosmic change, Shang oracle bone divination was often direct, personal, and focused on practical concerns of the present or near future. For example, in late Shang times,

the king and his court made offerings to the High God, Shang Di (Shang Ti), and to previous kings understood as deified ancestors. Lesser individuals made offerings to lesser spirits including nature deities and their own ancestors. In fact, ancestors may have been the most frequent intended recipients of sacrificial offerings, requests, and propositions presented to them and recorded on oracle bones. Sacrifices and offerings provide for gods and spirits, including ancestors who were thought capable of becoming gods or spirits with a continued interest in their descendants’ welfare. Divination could then be used to see if the offerings were well received. Satisfied gods and spirits can, in turn, assist humans with advice and beneficial intervention. Divination is then the art and science of interpreting their advice, predictions, or plans for intervention through a process of reading propositions, or charges; applying heat to rows of hollows bored into the back of the scapula or plastron; interpreting the resulting cracks; and thereby divining the success of the sacrifice or the recommendation of gods, spirits, or ancestors as well as whether they are likely to provide benefit or at least refrain from harm.

Translations of oracle bones demonstrate that these charges were often composed as rather simple statements. Numerous oracle bones record that the proposition was repeated two or more times in both its affirmative and negative forms to more fully verify the response divined from gods and spirits. Avoiding ambiguity in the proposition and repeatedly performing the charge in each of these forms is consistent with practical aims of sacrifice and divination in this era as opposed to the more abstract and philosophical readings, interpretations, and commentaries that develop around later forms of I-Ching divination.

While maintaining clear goals of present benefits, Shang divination did evolve. The last phases of Shang oracle bone divination are characterized by more scheduled charges to deified ancestors designed more narrowly and consistently to ward off harm or misfortune or to confirm good fortune rather than the format of paired affirmative and negative statements or the earlier breadth of divinatory topics. Nonetheless, the vast array

of oracle bone records demonstrate closely related religious and political concerns that emphasize the important role of proper ritual activity performed to please or at least propitiate gods and spirits. To propitiate is to appease or pacify gods or spirits who might otherwise be angry and might cause harm in their anger or dissatisfaction. There is clear evidence from later eras of Chinese history of related practices and relationships with gods, spirits, and ancestors who were understood to be active in the world and capable of both benefit and harm. Although oracle bone divination declined during the long Zhou period, these underlying principles continued to influence Chinese religious beliefs and practices in ways that remain evident today. As a result, divination and sacrifice remain popular even as religious practices shifted long ago from using scapulae and plastrons to divine the will of gods, spirits, and ancestors to using yarrow stalks, coins, or moon blocks (wooden crescents with convex and flat sides) to confirm divinatory messages.

Early Evidence of the I Ching

The *Yijing* (*I Ching*) is understood to be one of the most ancient and important texts of traditional Chinese culture. It has served as the key manual for divination for approximately three millennia. Moreover, it is an influential source for Chinese cosmology, the first of the Confucian classics, and a guide for individual situations and decisions that remains popular today. Modern scholars in China and abroad now reject traditional beliefs that *I Ching* divination originated with Fuxi (Fu Hsi), the divine culture hero who is also credited with inventing hunting, fishing, and the taming and sacrificing of animals at the beginning of the third millennium BCE. Although the earliest authors are unknown and modern scholars continue to debate dates for various layers of the text, most agree that the *I Ching* has provided guidance since early Zhou times (from near the turn of the second to the first millennium BCE).

Oracle bones provide records of widespread divination in China at least since the earlier Shang era, and the *I Ching* came to be understood as the oldest and most authoritative divination text. According to tradition, Fuxi invented *I Ching* divination and developed the eight foundational trigrams, each possible three-line combination of whole (yang) or broken (yin) lines. Traditional accounts suggest that this vertical set of three lines may have corresponded with the interrelated trio of heaven, humans, and earth. The trigrams endured but were later paired together into the full 64 combinations of six-line hexagrams.

The next three seminal figures in traditional accounts of the *I Ching*'s development are heroes of the Zhou era: King Wen, the Duke of Zhou, and Confucius. King Wen is said to have developed and ordered the 64 hexagrams including an interpretive judgment for each at the transition between the Shang and Zhou dynasties in the eleventh or twelfth century BCE. Consistent with divination elsewhere, these brief summaries of the meaning of each hexagram are open-ended and highly symbolic. Wen's son, the Duke of Zhou, is thought to have composed an analysis of each line of each of the 64 hexagrams.

➤ HEAVEN AND EARTH

Of the 64 hexagrams in the *I Ching*, the first two represent the extremes of yang and yin. The first, called *Qian*, doubles the trigram of heaven, three long unbroken yang lines over three more unbroken yang lines. Its associations are most purely yang with connotations of heaven, male, the ultimate source, and processes of more actively initiating, creating, transforming, asserting, and changing. The second hexagram, *Kun*, doubles the trigram of earth, three short broken yin lines over three more broken yin lines. Its associations are purely yin with connotations of earth, female, and processes of more passively responding, yielding, or receiving. The other 62 variously blend yang and yin lines and are consistent with Chinese cosmology, which sees natural patterns of change in accord with these two complementary yang and yin modes of vital energy, *qi* (*ch'i*). For example, the seasons in an annual solar cycle begin to move toward yin (dark, cold) after attaining the extremity of yang (light, hot) at summer solstice and then return back toward yang after the extremity of yin at the winter solstice. Similarly, the recommendations accompanying these hexagrams represent related complementary extremes rather than opposites, with one hexagram deemed positive

The eight trigrams of the *I Ching*.

and the other negative. Both indicate auspicious possibilities but recommend different ways to approach a situation consistent with more active and transformative yang characteristics or more receptive and harmonizing yin sensibilities.

—John Harding

Finally, traditional accounts maintain that a half millennium later Confucius wrote extensive commentaries on the *I Ching* known as the “Ten Wings.”

It is difficult to ascertain precise origins of the *I Ching*. While legends of Fuxi clearly belong to a mythological past, contributions attributed to King Wen and the Duke of Zhou could have originated at the onset of the Zhou era. These early Zhou dates for the *I Ching* are plausible but far from certain. Some scholars maintain that the text was a more recent product dating back only as far as the third century BCE, though this position emphasizes the text in a form that comes to have canonical status more than the earliest layers and origins of the *I Ching*. Scholars who favor either dates or positions in between agree in dismissing the traditional account that Confucius wrote the influential “Ten Wings” commentaries.

Naturally, the *I Ching* has changed significantly over time. In addition to various insertions of later language and values, the text evolved during the first millennium BCE from a guide for divination to an increasingly comprehensive compendium of advice and wisdom. We can also surmise how *I Ching* divination grew in complexity and scope. While early *I Ching* divination may have been closely related to the charges presented to the gods in oracle bone divination, later use of the *I Ching* divines the patterns of the cosmos in undulating and complementary alternations of yin and yang forces. Early means of this divination seems to have involved randomly selecting milfoil or yarrow stalks, some that were long and unbroken, signifying yang, and others broken off short, signifying yin. Each draw could then be represented with a long mark or two short marks (yang or yin), and the next yin or yang line could then be

written under the first. Two lines led to four combinations, and three lines yielded eight possibilities: the eight trigrams traditionally traced back to Fuxi. These eight trigrams were important from early on, and an elemental name drawn from nature was assigned to each: heaven, wind, water, mountain, earth, thunder, fire, and lake. The eight trigrams in turn were combined in each possible pairing to yield 64 hexagrams of six lines each. These have been the main units for divination from Zhou times to the present, with meanings attributed to each hexagram read line by line and read as a pair of trigrams with one element over the other.

Early interpretations coupled with commentaries from more than 2,000 years ago provide extensive guidance for the application of each hexagram. Whereas much divination with oracle bones served as a means for rulers to determine if their sacrifice had been accepted or to divine the answer to “yes or no” questions concerning key issues of state, the *I Ching* has long offered insights on these divinatory matters as well as insights into life decisions more generally for rulers and common people alike. Drawing stalks was not the only way to arrive at the six lines needed for each hexagram. Tossing coins is another way popularized since Sung times. Luminaries and literati of that age turned to the *I Ching* to better understand their world. Even today, commentaries, interpretations, and translations of the *I Ching* testify to its enduring influence and multilayered meanings for various audiences and practices, past and present.

Celestial Divination—Omens from the Sun, Moon, and Stars

“Enuma Anu Enlil” (“When the gods Anu, Enlil . . .”) is the first line of the mythological introduction to the Mesopotamian collection of celestial omens. Sometime during the second millennium BCE, Babylonian scribes wrote down these omens in cuneiform and organized them according to the different natural phenomena they describe. These phenomena include observations of the phases of the moon, lunar eclipses, solar phenomena (such as halos and sun dogs), solar eclipses, cloud formations and atmospheric phenomena, and the movements of the planets, such as Venus, in the night sky. Early astronomy in Mesopotamia was a mixture of precise observations and speculative thinking about the meaning of what happened in the sky. In the first millennium a tradition of mathematical astronomy evolved as a parallel discipline. Early on the various celestial bodies were identified with gods, and some subtle relationships appear to exist between the astronomical-astrological texts and literary narratives, but there is much we still do not know. Astrology as it is known today was practiced in Mesopotamia only sparingly in the first millennium BCE, but many of the Greek names for the signs in the Zodiac can be traced back to Mesopotamia. Ancient Babylonian scholars made note of the fixed stars, constellations, and planets, though naturally the planets were identified as different only by their movement, not their nature.

The two most prominent bodies in the sky were given important status as the objects of divination. Both the moon and the sun were closely observed and probably had been since at least the domestication of agriculture. Understanding the phases and path of the moon is a vital means of keeping track of time, which is necessary for a successful agricultural cycle. Any peculiarities in the color, shape, or appearance of the moon and sun were noted. For example, “If when the sun rises it is covered with a dark mist: There will be no rain.”

Rarer events were cause for even closer scrutiny. Thus, some of the earliest collections of omens describe lunar eclipses occurring on various days of the 12 Babylonian months. For example, during the fourth month, the summer month called Du'uzu (roughly June–July):

An eclipse (of the moon) takes place on the 16th of Du'uzu: There will be want of straw; downfall of cattle will take place; the cattle pen will be surrounded.

An eclipse (of the moon) takes place on the 20th of Du'uzu: Downfall of Elam; it will perish at the gate of the land.

An eclipse (of the moon) takes place on the 21st of Du'uzu: Adad will destroy the produce of the sea.

Eclipses of the sun were even less common. As anyone who has experienced a solar eclipse firsthand will attest, it is a singularly unsettling experience to see the sunlight fail in the middle of the day. It is not surprising that solar eclipses were typically viewed as dangerous events. For example:

First month: Nisannu (March–April)

If the sun is eclipsed in the month of Nisannu on the 1st day: The king of Akkad will die.

If it is eclipsed on the 11th day: A large army will be diminished.

If it is eclipsed on the 13th day: The king will go into exile.

Second month: Ayyaru (April–March)

If it is eclipsed on the 9th day: There will be famine.

If it is eclipsed on the 14th day: Rain in the sky will be scarce.

Ninth month: Kislimu (November–December)

If it is eclipsed on the 21st day: There will be headaches.

If it is eclipsed on the 16th day: Pregnant women will miscarry.

Eleventh month: Shabatu (January–February)

If it is eclipsed on the 11th day: An important person will perpetrate a rebellion in the palace.

Egyptian Magic

The use of "magic," or *heka* to use the Egyptian term, was understood as the de facto privilege of the gods, granted to mankind as a boon and a "weapon to ward off the blow of events," according to a wisdom text of the Tenth Dynasty (ca. 2156–2040 BCE). As opposed to the western (i.e., Greek and Judeo-Christian) intellectual tradition, the Egyptians made no practical or moral distinction between the mechanics governing religious rituals, medical practices, or magical acts. The same power was thought to underlie each of these activities, and this power was nothing less than the vital force by which the creator god set in motion the universe itself.

Egyptian magic was understood as a legitimate and effective means to attaining virtually any end. From the cares of the individual to those of the state, magic permeated all levels and aspects of society. In the private sphere, a large number of the preserved texts are concerned with practical matters of protection and healing. The most popular such spells concern warding off harm from all manner of sickness- and injury-causing demons; protection against dangerous animals such as scorpions, snakes, and crocodiles; and the protection of mothers and infants.

At the same time, offensive spells intended to bring about harm or force the compliance of another individual are also attested. In fact, the genre of love spells, which was of limited popularity prior to Greco-Roman times, consists entirely of injunctions against the desired individual, threatening horrible suffering and all manner of punishment should he or she fail to succumb to the magician's will.

At the state level, magical emphasis lies predominantly upon the destruction of enemies and foreigners. This practice is perhaps best exemplified by the ritual destruction of clay figurines inscribed with the names of foreign peoples (the so-called execration texts). Identical in intent if not outward form were the popular smiting scenes, which depicted the king holding a group of bound and conquered foes in one hand with a mace held poised to smash the enemies' skulls in the other hand. Such images were ubiquitous throughout Egyptian history and eventually found their way into private Greco-Roman love magic, where the magician's desired paramour took the place of the bound foreign prisoner. This ritualized torture of magical figures and images predates the medieval use of voodoo dolls by thousands of years and is demonstrably Egyptian in origin.

The mechanisms by which magic was made to work were quite numerous. The ritual destruction or torture of images, which were thought to be linked sympathetically with the desired victim, has already been mentioned. The same principal of like affecting like could also be used for protective means, as illustrated by the countless amulets designed for both the living and the dead, whose power derived from the object represented or some aspect symbolically associated with it. Spitting, licking, and swallowing formed another crucial means of activating magical power; in each case, the desired effect was predicated upon the concept of either ingesting magic or hurling it orally to either heal or harm. Another fundamental magical concept was the act of encircling (Egyptian, *pekyher*), which could manifest as a literal circumambulation or the drawing of protective circles.

Equally important as physical action were the words and incantations to be spoken (*djed-medu*) by the magician. While the specific phrases em-

ployed obviously varied from context to context, all genres of spells made frequent allusion to mythological events for the purpose of establishing a divine precedent to the desired outcome. To this end, the magician would often cast himself in the role of the relevant god or goddess, and injunctions of "It is not I who commands you, it is this god!" are common. Egyptians also recognized the magical efficacy of foreign languages, which occur as alphabetic transcriptions of otherwise untranslatable magic words.

Magic and Witchcraft in Mesopotamia

The practice of magic, the invocation of the supernatural to influence events in the human world, was an integral part of religion and medicine in Mesopotamia. It was not itself regarded as either good or evil but rather was defined by the purposes to which it was put. White magic was protective, used to treat bodily and mental ailments, to counter bad luck and bewitchment, to avert ill omens, and to ward off or counteract supernatural attacks by ghosts or demons, which were thought to cause illness and ill fortune. Black magic, though it called upon the same gods and utilized the same techniques as white magic, was intended to harm, often aimed at driving off the guardian personal gods of its victims and leaving them defenseless against ghostly or demonic attacks. Divination, the prediction of future events through the observation of natural phenomena, was generally distinct from magic although it did occasionally include magical practices such as necromancy: the raising of the dead for questioning.

► THE BURNING OF WITCHES

The practice of burning witches, especially widespread during the European Middle Ages, has a lengthy history. By the third millennium in Mesopotamia, witches using black magic were burned in person or in effigy. As death by burning barred an individual from the underworld that all humans otherwise entered, this forced the witch into limbo and rendered her magical powers useless. She was thus prevented from further tormenting her victims. Following the redefinition of the witch as a major adversary of the exorcist, she or a figurine representative of herself might still be burned, but this action was redefined as just another means of sending her to the underworld, which was now within the exorcist's sphere of influence.

—Karen Sonik

Prior to the second millennium BCE, magic was legitimately practiced by both private citizens and public officials. Witches, though capable of evil, often served as community healers, offering magical and medicinal treatments to those who had fallen sick. Their public counterparts were the exorcists (*āšiputu*), who magically treated illnesses caused by ghosts or demons, and the physicians (*asû*), who treated naturally occurring diseases with more mundane remedies such as potions and poultices. The division of labor between these two types of public officials was not absolute: patients could consult both an exorcist and a physician when the cause of their ill health was in doubt, and physicians could fortify or supplement their treatments with magical spells or incantations.

With the evolution of increasingly complex social, political, and religious institutions at the beginning of the second millennium, the practice and perception of magic changed significantly. Tzvi Abusch argues that the predominantly female witches and their unregulated magic came into conflict with the male exorcists, magicians who had gained legitimacy through their attachment to the temples. Many of the exorcists' rituals, previously intended to combat ghosts and demons, were reworked to also target witches, now depicted as malicious and illegitimate magicians intent on harming or destroying innocent

Amulet with a figure of a Lamashtu (the type of creature that it was designed to ward off), from Mesopotamia, around 800 BCE. This Lamashtu has the head of a lion, the teeth of a donkey, naked breasts, and the talons of a bird. She holds snakes in her hands and stands on her sacred animal, the donkey. A Lamashtu's principal victims were unborn and newborn babies. (Erich Lessing/Art Resource, NY)

victims. The most important antiwitchcraft text to survive is *Maqlû* (Burning), a compilation of incantations originally composed to combat miscellaneous supernatural forces. The combination of these incantations in the first millennium to form a single lengthy antiwitchcraft ritual attests to the fear of witches during this period. Additional magical texts existed to deal with other everyday worries. A collection of spells known as *Šurpu* (also translated as “Burning”) was intended to purify individuals of any moral infractions they had intentionally or unintentionally

committed, keeping them in good standing with their protective personal gods.

Magic was not only verbal in Mesopotamia but also was visual. Amulets and apotropaic figures were common in all periods, although Neo-Assyrian examples are especially well known. Amulets, often worn around the neck, could combine text and image, being inscribed with protective incantations and bearing images capable of warding off evil. Magical figures, often monstrous or demonic in form, were buried in architectural foundations, stood at the gates or doorways of temples, and appeared frequently on the wall reliefs decorating the Neo-Assyrian palaces. Their terrifying appearance was thought to be especially efficacious in warding off other dangerous supernatural forces.

The Wu (Shamanic) Tradition in China

The most popular religious practice in China 3,000–4,000 years ago was the *wu* (shamanic) tradition, and magic and witchcraft were a part of it. The *wu* (shamans) were prominent religious and political figures as well as healers during the Shang dynasty (1600–1066 BCE).

Most English publications describe the *wu* as wizard, witch, sorcerer, shaman, medium, or magician. Their role in ancient China, however, was much more expansive than such terms might imply. The commonly accepted translation for the ancient *wu* is "shaman" or "shamanic" because

they played similar roles in rituals and healing. As recorded on oracle bones and in writings from more than 3,000 years ago, the *wu* were ritual specialists, diviners, imperial officers, and healers. At the time, *wu* (shaman) and *yi* (healer) referred to the same person. The classical Chinese writing for healing (*yi*) even contains *wu* as a part of the character.

The *wu* were the first professional healers and ritual leaders in ancient China. Because they were considered to have special knowledge and supernatural powers, some of them were appointed imperial officers during the Shang and early Zhou dynasties (1600s–771 BCE). In these positions, they conducted imperial rituals and divinations for military operations.

Most contemporary researchers inside and outside China agree that the *wu* tradition laid the foundation for early Chinese civilization. Some argue that the *wu* were the earliest Chinese intellectuals and played a fundamental role in advancing astronomy, healing (both spiritual and with medicine), and folklore. The *wu* are known to have contributed to anonymous classics such as the *Book of Changes* (*I-Ching* or *Yi Jing*) and the *Classic of Mountains and Seas* (*Shang Hai Jing*).

It is uncertain when the *wu* first achieved important roles in Chinese history, but records show that they had great influence during the Shang and early Zhou dynasties. Later, Daoism (Taoism) and Confucianism emerged, and technological advances were made in many areas. Traditional Chinese medicine gradually became a profession, and there were medical officers at the imperial court and local levels. Because of this development, the remaining *wu* gradually lost their power in the healing tradition and political system.

The *wu* tradition, however, had a great impact on the evolution of the Chinese civilization for many centuries. It merged with the dominant political system, enriched traditional Chinese medicine and folklore, and gave rise to Daoism.

■ Introduction: Ancient Near Eastern and Mediterranean Literature

Soon after the invention of writing in the ancient Near East came the first florescence of world literature. The writing of the Near East (and perhaps the Mediterranean, depending on when one dates Homer's works) is the earliest body of literature in human history. From this body came many genres of writing that are still used today as well as many that have been abandoned. Economic texts, administrative texts, and legal texts fall within this time period and are dealt with elsewhere in the encyclopedia. Religious texts including hymns, mythological accounts, creation stories, ritual guides, and votive inscriptions all reflect written expressions of human understanding of the divine. Scientific texts and religious texts are difficult to differentiate, as both reflect conscious attempts to understand the world and record these observations in writing. The first letters between friends, family members, and strangers appear at this time along with the first diplomatic cor-

respondence. The first historical texts were written, as were the first texts meant to commemorate important events. Biographies recorded the lives of individuals, some fictional and some accurate. And tales of heroic figures like Gilgamesh entertained and instructed ancient audiences.

Who the audiences for these texts were is less clear. Many texts are found walled up within buildings or sealed within tombs; undoubtedly these were intended to be read by the gods or by the dead. Other texts have been preserved as school practice texts, copied over and over again by students learning how to write at the scribal academies. Given how few people actually would have been literate, it is thought that much of this literature was intended to be read aloud. In some instances, these written versions of stories were probably based on originally oral compositions.

—Kevin M. McGeough

➤ THE TROUBLE WITH TRANSLATION

Historians who wish to use ancient literature should heed a few warnings if they intend to work from translations of ancient texts (although a good historian should become familiar with the languages of the time and the place of study!). Remember, a translation of an ancient text is actually a modern piece of literature, and depending on how true to the original source the translator was, the translation could vary significantly. Since most of the languages of this period were forgotten and relearned, there are many words that still remain obscure and grammar that is incomprehensible. A translator does his or her best to understand these, but there is much room for error. Often texts are not fully preserved. Where there are breaks in an ancient text, a modern translator usually places square brackets: []. All of the writing found within the square brackets are reconstructions made by the translator. Sometimes

these are very trustworthy, since ancient writers were fond of repetition. But beware of any translation with too many square brackets! It is not just our understanding of ancient languages that is imperfect; our understanding of ancient context is also problematic. The context of these texts is very different from the modern one: many of the values and ideas of ancient literature feel remarkably alien, and any attempt to harmonize these values with modern ones is misguided. Joseph Campbell, who wrote popular accounts of mythology, habitually oversimplified ancient literature to make it seem more like modern writing. Thus, any of the conclusions he drew about ancient literature are really just conclusions about his own renditions of the stories. Be very careful with any translation: read the critical notes, and do not trust the translator.

—Kevin M. McGeough

Egyptian Literature: Love Poetry

Love poetry from ancient Egypt presents variations on the theme of love and how it is experienced, although the actual term for love (*meri*) appears somewhat infrequently. These lyrical compositions were termed “utterances” or “songs” by the Egyptians themselves. The latter term is appropriate, as they were likely sometimes sung or chanted with musical accompaniment. Four primary compendia survive in varying states of preservation: three collected on papyrus documents and one carried on a broken vase. All are written in the Late Egyptian phase of the language and date from the Nineteenth and Twentieth Dynasties of the New Kingdom (roughly 1300–1100 BCE).

Ancient Egyptian lyrical style does not appear to have been dictated by one set of rigid structural rules. Rather, it seems to have had a freedom of form similar to lyrics of modern rap compositions, as Redford has suggested. Arrangement by couplets, though, appears to have been one favored approach, and some poems are divided into cohesive stanzas of variable length. Although phrasing reflects an economy of words, these are not simplistic compositions. Literary devices such as complex puns and wordplay appear, and translation is not always straightforward.

Narration of most love poems is in the first-person voice. A poem is usually fashioned as the monologue of a love-struck young man or woman or rarely both alternating between each other (but still not as a dialog). In an exceptional group of poems, speakers take the form of trees in an orchard or garden, some telling of couples who meet under the shade of their branches. Those in love refer to each other as brother or sister, here meant to stress the intimate closeness of two people rather than to indicate family relationship. In almost every case the reader is provided with neither the name of the narrator nor the object of affection. The tone of the poems ranges from lighthearted and playful to serious and pining.

Unlike many genres of ancient Egyptian literature, the content of most poems does not seem especially foreign to the modern reader. Common themes include love sickness, being ensnared by love (or one's lover), admiration of a

➤ A LOVE POEM FROM PAPYRUS HARRIS

The discomforting symptoms of intense longing for love, often called love sickness, is a recurrent theme in poetry through the ages. In this brief example from ancient Egypt the narrator puts a novel spin on this motif by faking sickness as a ruse to attract his beloved:

“I will lie inactive at home,
And I will pretend to be sick.

And then my neighbors will enter to look,
And my sister will be among them.

And she will send the doctors out,
For she knows my malady” (translation by author)
—Nicholas S. Picardo

(Original hieroglyphs from p. 73)

lover's desirable features, wishes to be closer to the object of desire, frustration over awaiting a lover's return home, a rendezvous, reluctance to depart from a lover's side in bed, and effusive professions of love and devotion. Often an emphasis on spontaneity and the physical side of love and intimacy is detectable, reinforced by both subtle and explicit allusions to anatomy, fertility, and productivity.

Hymns and Wisdom Literature

A substantial part of Sumerian literature is made up of hymns, addressed to individual gods and to their temples. The earliest surviving hymns (and also the earliest literary work whose author is known) were composed by Enheduanna, daughter of Sargon of Akkad and entu-priestess of Nanna at Ur, who also edited a collection of hymns. In one Enheduanna paints a picture of the magnificence, power, awesomeness, and unpredictability of the goddess Inanna, manipulating the great gods who dare not take a decision without her approval, controlling the lesser deities, ferocious in her wrath, raising the lowly and abasing the lofty. In another, *The Exaltation of Inanna*, however, Enheduanna rages about her expulsion from the temple by Lugalane (leader of a revolt against Naram-Sin), exhorting the gods, Inanna, Nanna, Enlil, and An, to recognize Lugalane's impiety, turn their hearts toward her, and restore the status quo.

A number of Lamentations, poems dating mainly from the late third and early second millennia, were also concerned with the way the will of the gods was reflected in human destinies. They began by painting a picture of desolation in a city forsaken by the god, the people dead in the streets, the buildings torn down or in flames, the empty fields choked with weeds, and foreign troops spreading carnage. Then the spirit of the poem lightened: the gods had relented, and the city and the land were being put to rights. The context of these poems was probably the restoration of temples and other sacred buildings after their destruction in warfare. The fate of the city was bound up with the will of the gods: its fall reflected their displeasure, its restoration the return of their favor. Later compositions in this genre, not related to specific cities, became part of the liturgy, performed on certain days in the cultic calendar. Laments were also composed to mark the death of Dumuzi or the passing of kings, the latter perhaps modeled on the Sumerian poem lamenting the death of Gilgamesh.

Individual illness and misfortune were also seen as coming from the gods as punishment for known or unwitting faults. Medical treatment by the exorcist or the doctor involved the recitation of incantations and formulaic prayers, emphasizing

the sufferer's piety, expressing contrition for any offense they might knowingly or unknowingly have committed, praising the gods, and begging for the punishment to be lifted. Sumerian and Akkadian literature contains many such prayers. These might also be addressed to the gods in the form of letters, written by a scribe and laid before the god's image.

In the later second millennium, scholars developed the philosophical train of thought of these prayers, exploring the inscrutability of the divine mind in a number of poems, including "Ludlul" and the "Babylonian Theodicy." These are the major works in what is known as Wisdom Literature, a genre of reflective writing that also includes collections of Sumerian proverbs, riddles, and fables as well as disputations in which various materials, such as copper and silver, tools, plants such as Datepalm and Tamarisk, animals, and other features of the natural world such as Winter and Summer, debated their relative importance, putting forward their own merits and disparaging their rival. One collection of proverbs and wise advice, the "Instructions of Shuruppak," couched in the form of a father's instructions to his son, was among the texts known from Early Dynastic Shuruppak and Abu Salabikh.

The World's First Author, Enheduanna

The Akkadian priestess and poet Enheduanna is one of the first known authors of literature whose

name has survived. She thrived in Mesopotamia in circa 2334 BC, after her father, Sargon of Akkad, conquered a large portion of Mesopotamia and established one of the world's first great empires throughout the Tigris-Euphrates Valley and up into present-day Turkey. At the time, each city in the region worshiped its own god or goddess, who seemed particularly to protect the residents of its city. Sargon faced the problem of how to unite the peoples of his expanded kingdom, and he chose religion as the unifying principle. He assigned the task of unification to Enheduanna, who performed the job with astonishing creativity and success.

Enheduanna served as high priestess of the Sumerian goddess Inanna, the queen of heaven, and also fused that worship with the praise of the Sumerian goddess Ishtar. The advocacy of the supremacy of Inanna over the other gods served as a religious counterpart to Sargon's political empire. Enheduanna proved so successful in joining the worship of the favorite goddesses, thus linking people's political loyalties to some degree, that Sargon's successors continued the practice of making their daughters high priestesses and thus forging a link between the cultures of the region. That political and religious accomplishment is remarkable enough, but Enheduanna distinguished herself in another way. She wrote magnificent poetry in praise of Inanna, and that poetry has survived today, making Enheduanna the earliest known author of literature.

Enheduanna's most famous poems are her cycle of hymns to Inanna. Those hymns provide a glimpse into the religious feelings of the ancient Sumerians and also show the transformation of religious interests on the part of Enheduanna. In the first hymn, "The Myth of Inanna," Enheduanna almost exclusively celebrates the goddess's power; Inanna is portrayed as a fierce warrior goddess who crushed the people of Mount Ebih. This hymn may refer to a historical event commemorating one of Sargon's triumphs, and if so it serves as a perfect fusion of political and religious propaganda promoting the rule of Sargon and Inanna. Sargon's priestess-daughter served her function beautifully. The poetess departs from this traditional warlike function of the goddess in her second hymn, "Stout-Hearted Lady," for in this her principal theme is Inanna's omnipresent role in human affairs. Once the political

conquest is over, the goddess and the ruler are involved in governing.

Narrative Literature

The deeds of heroic mortals were the subject of many Mesopotamian poems. Some were originally historical figures, embellished versions of their lives woven into folk stories or later propaganda. The earliest surviving poem, dated before 2500 BCE, concerns the adventures of King Lugalbanda of Uruk. The stories of Lugalbanda's son Gilgamesh were particular favorites down through the ages.

Stories probably dating from the Old Babylonian period recount the obscure birth of Sargon of Akkad, son of a priestess and an unknown man from the mountains, who was cast adrift on the river in a basket and rescued by a palace gardener in Kish. Growing into a youth personally favored by Inanna, he becomes the king's cupbearer. The old sick king soon conceives a secret hatred for the golden youth and attempts to kill him by various means, but Inanna's advice saves Sargon every time. Eventually the king of Kish is deposed, and Sargon's rise to power begins.

Sargon is the great heroic king who is favored by the gods and is the founder of the first empire in Babylonia. All that was considered good about this empire was attached to him in later times, embellished by legend. In another poem, "King of Battle," he personally leads an expedition to rescue merchants trapped in the Anatolian city of Burushkhanda. Here the heroic image of Sargon is polished up to support the activities of a later king, Shamshi-Adad. In contrast, in the poem "The Curse of Akkad," probably

composed in the Ur III period, Sargon's grandson Naram-Sin is depicted as the antihero, sacrilegiously opposing the will of the gods. Fragments of history are woven into these tales, but they are manipulated for the sake of the story and the moral that it has to convey.

In the late second millennium, many Babylonian cities were sacked, part of a wider picture of international disintegration. These disasters and the people's sufferings may have been the inspiration for the magnificent poem, the "Epic of Erra," composed by Kabti-ilani-Marduk (probably fl. ninth or eighth century BCE) who claimed that it had been revealed to him in a dream. In this, Erra (Sumerian Nergal), god of plague and strife, by subterfuge obtains the opportunity to create universal chaos, inciting wars, rebellion, and savage reprisals; killing people and animals; destroying cities; and promoting sacrilege. The other gods abandon their cities, sick with disgust at the wanton destruction and anarchy. Erra exults in the universal devastation but is eventually persuaded to turn his savagery upon an external enemy.

The actions of the gods were explored in a wealth of mythological poetry, retelling stories probably familiar to every Mesopotamian in oral form. Some dealt with how the world was created, ordered, and peopled. These included *Enuma Elish*, the great Babylonian poem composed in the late second millennium that tells how Marduk saved the gods from destruction and thereafter set the world in order and created humanity. In an earlier Sumerian poem, "Enki and the World Order," it is Enki who allots to every part of the world its characteristics and to each deity his or her sphere of influence.

Other poems tell the story of individual deities. Many revolve around the seductive, capricious, and at times terrifying and merciless figure of Inanna: the adolescent courted by her future husband in a pastoral idyll, the calculating young goddess determined to win the benefits of civilization for her own city, the woman scorned exacting her vengeance, the greedy goddess demanding additional powers from Enki, the enthusiastic patroness of sexual indulgence in all forms and the magnificent tutelary deity of the glorious new city of Akkad.

Historical Texts

Sifting the historical truth from a diverse range of sources is a task that has occupied many students of Mesopotamia's past. Literary compositions such as The Legend of Sargon and The Curse of Akkad are largely unhistorical, although there may be fragments of historical information within them. More subtly, genuine contemporary historical records might also contain both truth and spin, because they were often intended not only to record the achievements of rulers, individuals, or communities but also to present their actions in a favorable light to both human and divine audiences. Much historical information can also be gleaned from more mundane written sources, such as letters and legal and economic records.

The earliest written materials, from the late Uruk and Jemdet Nasr periods, were mainly economic and administrative documents. Early Dynastic texts also included historical, religious, and mythological compositions. From the Ur III empire there is an enormous number of administrative documents, recording economic and personnel matters in meticulous detail, and a few literary works. Many other compositions of these and earlier periods survive as copies made in the Old Babylonian period, including mythological and historical poems, law codes, and religious texts. Even the latter often contain some historical material. For example, poetic lamentations described the destruction and rebuilding

of particular cities, couched in terms of the withdrawal and restoration of the gods' favor but reflecting the troubled conditions of the period, when city-states warred among themselves and were subject to devastating attacks by external enemies. A growing body of Akkadian literature accumulated through the later second and first millennia, among them epic poems about historical monarchs, including fictive autobiographies.

Scribes and scholars often composed works in imitation of earlier texts, drawing on and adapting earlier material for contemporary purposes. The Sumerian King List was probably composed in the Ur III period to emphasize Ur's place in the divinely ordained scheme whereby from hoary antiquity a principal city was given rule over all the cities of Sumer and Akkad, an anachronistic fiction. One Old Babylonian text, known now as the Weidner Chronicle, was a piece of religio-political propaganda in the form of a letter to a king pointing out the disastrous fate of former kings who had failed to honor Marduk's temple in Babylon (a city that in reality had not existed in the time of these earlier kings). Also composed by scribes following genuine earlier historic models was *Naru* literature (Akk. *stele*): spurious documents purporting to be copies of royal inscriptions that were produced by royal scribes for the purposes of propaganda, storytelling, or justifying current action or argument on the basis of falsified or misused ancient precedents.

Beginning with Uru-inim-gina of Lagash in the twenty-fourth century BCE, kings occasionally issued law codes, policy statements in which they laid down some rules of conduct and appropriate punishments for crime. Many other legal documents survive. These include court records and private deeds and contracts. More obviously historical are the international agreements, treaties, tribute lists, and other texts devoted to relations between states.

Royal inscriptions began in the Early Dynastic period with simple dedications of objects or structures by a named monarch to a deity but by the late Early Dynastic period had developed into considerable narrative descriptions. Royal propaganda grew progressively more detailed, eulogizing the military and civil achievements of

the king. By early Neo-Assyrian times, substantial records were created as texts and inscriptions, giving full details of campaigns and other achievements. The great reliefs on the walls of the Assyrian palaces provided a particularly vivid visual message: reassuring citizens of the power and piety of their ruler and the effectiveness of their army and striking terror into the hearts of visiting foreigners. Great public works, such as the creations of canals, were also the subject of Assyrian and Babylonian inscriptions.

Gilgamesh

The Sumerian and Akkadian cuneiform legends about Gilgamesh are arguably Mesopotamia's most enduring and most approachable contribution to world literature. The Babylonian *Epic of Gilgamesh* is a literary masterpiece that should be counted among other ancient classics such as Homer's *Odyssey*, the *Mahabharata*, and *Beowulf*. The literary traditions about Gilgamesh deal with many basic themes familiar to the human experience: political oppression, the dynamic between civilization and wildness, sex,

➤ GILGAMESH AND THE FLOOD

Tablet 11 of the first-millennium Standard Babylonian *Epic of Gilgamesh* contains a version of the Babylonian Flood myth. This composition was not original to the Gilgamesh stories but was borrowed from the Akkadian composition about Atrahasis, who is said to have survived the flood. In the *Epic of Gilgamesh*, the hero who tells of surviving the flood is named Utanapishtim, meaning “I/He has found life.” At the beginning of Tablet 11 of the epic, Gilgamesh has traveled to the ends of the earth and found Utanapishtim, who gains immortality by surviving the flood. Gilgamesh is told the story of the flood and realizes that Utanapishtim’s immortality was simply a one-time event and that he possessed no secret of immortality. The exhausted Gilgamesh then falls into a deep sleep. Upon waking Gilgamesh realizes that he is destined to die a mortal death. Utanapishtim gives Gilgamesh one last chance and tells him of a sea plant that provides rejuvenation. Gilgamesh finds and loses the plant and ultimately returns home to Uruk, where he climbs the city walls to look out over his city.

—Matthew T. Rutz

friendship, adventure, violence, grief and loss, and facing the limits of human mortality.

According to literary sources Gilgamesh, king of Uruk, was two-thirds god and one-third human. He was said to be the offspring of the king Lugalbanda and the goddess Ninsun. So far there is no evidence for a real historical Gilgamesh, but it is quite possible that a leader by that name did exist. If Gilgamesh was a historical figure, he would have reigned sometime around the first quarter of the third millennium BCE. The first large collection of Sumerian and Akkadian literature about Gilgamesh is from the Old Babylonian period (ca. 1900–1600 BCE). Sometime during the second millennium the Akkadian Gilgamesh texts were organized and expanded into the 12-tablet epic that was transmitted throughout the first millennium.

The Sumerian Gilgamesh cycle consists of six separate literary narratives, all of which were composed and copied in the Old Babylonian period (ca. 1900–1600 BCE). In the tale known by

modern scholars as Gilgamesh and Agga Gilgamesh is threatened by an attack from Agga, ruler of the city-state Kish. Gilgamesh is able to bring together the assembly of young men to defeat Agga, but it is Gilgamesh’s radiance that eventually cows Agga. In this tale Enkidu is Gilgamesh’s servant, not his companion. In “Gilgamesh and the Bull of Heaven” the goddess Inana offers herself in marriage to Gilgamesh, who refuses. Enraged, Inana gets the Bull of Heaven from her father, the sky-god An, and the divine bull attacks the countryside around Uruk. Gilgamesh and Enkidu confront and kill the bull, and Gilgamesh offers the bull’s horns to Inana’s temple in Uruk. In *The Death of Gilgamesh* Gilgamesh lies on his deathbed while the gods debate his destiny. Gilgamesh then dies and is made a god of the underworld. The people of Uruk build Gilgamesh a tomb and bury him. In the tale Gilgamesh, Enkidu, and the Nether World Gilgamesh makes furniture and sports paraphernalia for himself using a special tree of Inana. While Gilgamesh and Enkidu are playing, the ball and stick fall through a crack into the underworld. Enkidu chases after them but then gets stuck down in the underworld, a common motif in Mesopotamian mythology. The god Enki assists Gilgamesh and allows him to talk with Enkidu’s ghost, who tells Gilgamesh all about what it is like in the underworld. “Gilgamesh and Huwawa” circulated in two versions that had both major and minor differences in plot. Gilgamesh leaves Uruk to cut down cedar trees and create an illustrious reputation for himself. He is attacked by the fearsome forest monster Huwawa, whom he defeats using his wits and takes captive. Against Gilgamesh’s wishes, Enkidu then kills Huwawa. Only “Gilgamesh and Agga” and “The Death of Gilgamesh” do not have Akkadian-language parallels in Mesopotamian literature.

In the early second millennium Akkadian-language stories about Gilgamesh also circulated in written form. Only a few substantial fragments from this period have been found. It appears that in some scribal centers a unified Gilgamesh literature began to take shape in the early second millennium BCE, and the ancient Babylonians referred to this composition by the name *Surpassing All Other Kings*. In subsequent Babylonian tradition the compilation of the *Epic of*

Gilgamesh was attributed to a scholar named Sin-leqi-unninni about whom virtually nothing is known. This version consisted of 12 tablets, which can be thought of as being almost like chapters. For instance, Tablet 11 contains a version of the flood story. Tablet 12 is almost like an appendix and contains an Akkadian version of some of the Sumerian myth Gilgamesh, Enkidu, and the Netherworld. At present only about three-quarters of the epic are preserved, although future discoveries may eventually allow us to reconstruct the whole narrative. The *Epic of Gilgamesh* was called “He Who Saw the Deep” and also simply “Series of Gilgamesh” in ancient Babylonia. All of the manuscripts for the *Epic of Gilgamesh* come from the first millennium BCE, but many elements of the epic can be found in the fragmentary Old Babylonian stories, such as the episodes involving Enkidu, Huwawa, and Utanapishtim. The epic was probably compiled during the later second millennium BCE, when many works of Babylonian literature were organized and edited.

The *Epic of Gilgamesh* links together all of the known Akkadian episodes into a coherent whole. Gilgamesh, king of Uruk, oppresses his people, driving the gods to create for him a fitting rival, the wild man Enkidu. In a dream Gilgamesh foresees the coming of Enkidu, who is raised by animals. A prostitute from the city seduces him and makes him civilized. Gilgamesh and Enkidu do battle and then become fast friends. Together they embark on an adventure to cut down cedar trees in the cedar forest, which is guarded by the fearsome divine protector Humbaba, whom they slay. After the two have returned to Uruk, the goddess Ishtar propositions Gilgamesh, who rebuffs her advances. In a fit of rage, Ishtar sends the Bull of Heaven, which Gilgamesh and Enkidu slay. Because of these actions, the gods sentence Enkidu to death, and he becomes ill. When Enkidu finally dies, Gilgamesh is bereft at losing his friend, becomes terrified of death, and sets off on a quest for immortality. He crosses the Waters of Death and comes to the dwelling place of Utanapishtim, who has survived the Flood and gained immortality. Utanapishtim reveals to Gilgamesh that there is no secret way of attaining immortality. By grasping his mortal limits Gilgamesh gains

wisdom, and when he returns home to Uruk he sets down his story for future generations.

Ugaritic Literature

The inscriptions found at modern Ras Shamra (ancient Ugarit) near the Mediterranean coast of Syria from 1929 onward have revolutionized the world of Near Eastern studies. Not only did the West Semitic language of Ugarit comprise one of the earliest known alphabetic scripts (roughly the fourteenth and thirteenth centuries BCE), but much of its contents was closely related to the Hebrew Bible (Christian Old Testament) in both language and literary themes. Even if Ugaritic literature is incomplete in comparison to the Hebrew Bible, it represents the only other corpus of Syro-Palestinian literature from pre-Hellenistic times. Eight languages other than Ugaritic are used in the texts from Ras Shamra. They are normally encountered in texts concerning ordinary day-to-day affairs (i.e., administrative, legal, and epistolary texts). In sharp contrast, the ritual and literary texts of local custom and belief are written solely in Ugaritic.

Although there are many types of prose besides literary texts—divinatory, astrological, ritualistic, medical, and lexical texts—the literary genre of mythology has had special impact on

➤ UGARITIC RITUAL TEXTS

It is tempting when reading Ugaritic literature (e.g., *The Baal Cycle*, *Aqhat*, and *Keret*) to give interpretations to the texts from the cultic affairs practiced at the city of Ugarit. There is a sound basis for this interpretation, since nearly all of the mythological texts are religious in nature and at least in one instance are explicitly combined with ritualistic liturgy. Such is the case for *The Birth of Shahrū and Shalimu*, a text that does not correspond to the mythological texts just mentioned but is still ostensibly literary in character. It has been interpreted in terms of sacrificial rites (mainly with regard to the agricultural diet) and possibly even in terms of sacred marriage rites. Besides the allusions in mythological literature, there are more than 100 explicitly ritual texts from Ras Shamra (ancient Ugarit), most of which are written in the local Semitic dialect known as Ugaritic. They are brief. Typically, a text lists an animal along with a deity and the specific type of sacrifice. That ritual played an important role in the development of Ugaritic literature cannot be denied. It must be conceded not only that those who were writing and copying the texts were closely tied to the temple but also that the populace at large was heavily imbued with religious and ritualistic dispositions. The relationship between *Mythos* and *Ritus* (myth and ritual) is intriguing indeed.

—Benjamin D. Thomas

Ugaritic studies. Three stories in particular have gained much attention, all of which were likely copied by the famous scribe Ilimilku. They may all be classified within the genre of myth: any text centered upon a deity or hero. The first, *The Baal Cycle*, is made up of a series of myths surrounding the central West Semitic deity of Ugarit, the storm god Baal, and recounts his victory over Yamm, god of the sea, for kingship of the cosmos. Next Baal has a palace built to vaunt his newly attained position of king. Finally, he does battle with Mot, the god of death, a story that reflects the reality of the vegetational seasons.

Kirta narrates the story of a king whose dynasty has almost perished, and because he is bereft of children, it is mended with the aid of the creator god El. El tells the king to appeal to Baal

Poem about the death of Baal, fragments of a tablet from Ugarit (modern Ras Shamra), fourteenth century BCE. (Réunion des Musées Nationaux/Art Resource, NY)

and instructs him to march the entire population to a foreign town to take a bride who would provide him a family. The plan meets with success, and she bears him eight sons and eight daughters. Unfortunately, as King Kirta has forgotten to fulfill a previous vow to the goddess Asherah, she vexes him with a deadly illness, reflected in nature in the form of a drought.

Aqhat is similar to the former in subject matter. The hero, Danel, is childless. He performs a ritual, inciting Baal to respond. Baal beseeches El to provide Danel a son. After Danel receives his son, Aqhat, the subject of the next scene is the bestowal of a bow forged by the craft gods, Kothar and Khasis, onto Danel, who in turn bestows it upon Aqhat. Aqhat appears then before the goddess Anat, who covets the bow, offering Aqhat first silver and gold and then immortality. Aqhat refuses, and Anat has him assassinated. The story breaks off with Aqhat's sister in pursuit of her brother's assassin.

The stories hold in common themes of kingship, longevity, and bereavement of or appeal for offspring. Of special importance is the resemblance between the stories and the vegetation cycle, one that also had significance for the cult at Ugarit. Moreover, these themes remain important for biblical as well as for Greco-Roman literature. We may immediately recognize ar-

chetypal characters similar to Abraham, David, Job, Apollo, Andromeda, Dionysus, and Perseus, among others.

More formally, Ugaritic literature tells a story but in highly literary language, calling to mind the epic poetry of Homer. Characteristic of West Semitic poetry is the exhaustive use of the poetic device known as parallelism (A // B), for example:

I'll let you count years with Baal,
With the son of El will you count months.
ašsprk. 'm. b'l šnt = A
'm. bn il. tspr. yrb}m = B

Line B mirrors or is parallel to line A. Both A and B have the verb “to count” (*spr*). A reads “years” and B uses “months,” but each of them corresponds to units of the calendar. A says “Baal,” and B expands the latter by the title “son of El.” They each refer to the same deity, but the second employs the father/son imagery in terms of the head deity El, typical in ancient Near Eastern mythology when a deity-king has risen after his father. Not only is there semantic parallelism, or parallelism between the meaning of words, but there is also syntactic parallelism wherein the grammatical structures are (nearly) identical. Although the word order is distinct in the Ugaritic lines, the basic underlying structure is: verb (*spr*) + preposition (*'m*) + proper-noun (*b'l // bn il*) + object (*šnt // yrb}m*). This type of parallelism is even more recognizable since the same verb and preposition combination is present in both lines. In sum, Ugaritic literature continues to bring into sharper relief aspects of ancient Semitic poetry.

Hittite Literature

The cuneiform wedge-shaped writing system was first introduced to Anatolia in the early second millennium by the Assyrian merchants who had set up trading colonies near the city of Kanesh, but the earliest surviving archives in Hattusha were written by scribes who lived more than a century after the destruction of the trading colonies and were trained in the Old Babylonian script. Nevertheless, Hittite literature may have begun in Kanesh since the Hittites refer to their language as Neshi, the language of the city (Ka) nesh. The documents from Hattusha include edicts, annals and chronicles, sagas and epics, and myth and rituals as well as hymns, wisdom literature, and law collections. Not only have the Hattusha libraries provided native Hittite history and literature, but many older Hattic and Hurrian documents have survived in Hittite or in bilingual texts as well, providing windows into these lesser-known cultures.

Like the political and social institutions of the Old Hittite Kingdom, the earliest Hittite literature appears in a fully developed form, the previous stages wholly lost to us. The oldest extant Hittite text, and thus the oldest extant Indo-European text, is the Proclamation of Anitta of Kussar. Anitta himself relates the history prior to the founding of the Hittite state through his series of victories and devotion to the storm god. Ironically, Anitta condemns the city of Hattusha, which would become the Hittite capital and is where the tablet was found. In their own proclamations and annals as well as in later legendary narratives, early Hittite kings are portrayed as confident and wise rulers. In legend, Hattushili I traveled to the end of the world, where he encountered cannibals, and once “he became a bull” with “horns . . . slightly curved” as he charged through the Taurus Mountains against the Aleppo Army. Another story resembles the David and Goliath legend. Hattushili's chariots are outnumbered more than seven to one against the Hurrians at the Siege of Urshu, so he risks his life in one-on-one combat with the enemy's champion to secure his troops' safety. These portrayals of the king fit in well with a larger reoccurring Hittite theme of liberation and release. These themes are also found in anecdotal

➤ KUMARBI

Originally a Hurrian myth, the Kumarbi Cycle is celebrated as a second-millennium Near Eastern link with Hesiod's Theogony; however, whether the Greeks learned the myth from Hittite merchants or simply inherited the myth from a common background is unknown. The myth begins with the succession of four generations of ruling gods. Nine years after Anu (the personification of Heaven), the Hurrian counterpart of Greek Ouranos, usurps Alalu's throne, Kumarbi usurps Anu by biting off his manhood. However, Anu warns that Kumarbi, Kronos's counterpart, will eventually be overthrown by the storm god Teshub, Zeus's counterpart. Another similarity may include Kumarbi's wish to eat his offspring, as does Kronos, although any conclusion is tentative since the text is fragmentary at this point.

—Spencer L. Allen

admonitions and wisdom literature, which further stress the rewards of the good life and punishment of evil deeds.

The myths and rituals form a natural pair in Hittite culture and comprise most of the surviving Hittite texts. The mythic structure consists of a simple two-part scheme. First, an event disturbs the natural cosmic order, and then a deity intervenes to reestablish the proper order. The ritual recorded along with the myth functions as the mechanism by which the deity is prompted to action. For instance, the myth of the Disappearance of Telipinu describes how when the angry storm god Telipinu vanished the crops stopped growing, the earth dried up, and the gods and humans began to die of hunger. Upon his return, prompted by a bee sting, he was offered a dozen rams and other offerings in order to calm his anger and restore health to the land. The ritual aspect of this text, the bulk of the text, appeals to the angry god and effects his return and calm, ensuring humanity's and the god's survival.

Homer

Greek literature begins with Homer, a semi-mythic, supposedly blind poet who composed the *Iliad* and the *Odyssey*, both several thousand lines long and rendered in dactylic hexameter. The *Iliad* records a brief episode in the last year of the Trojan War, when "the Best of the Achaeans," Achilles, got into a spat with the "King of Men," Agamemnon, over the woman Briseis. Infuriated that Agamemnon took Briseis from him, Achilles refused to join his comrades, the Greek Army, in battle while simultaneously asking the gods to give extra strength to the Trojans. The Greeks—called Achaeans, Argives, and Danaans—suffered so terribly at Trojan hands as a result that Achilles' close friend Patrocles finally disguised himself as Achilles to frighten off the enemy. Unfortunately, in so doing he was mistaken for Achilles and was killed by the best of the Trojans, Hector. This angered Achilles even more than the loss of Briseis; he reentered the war and killed Hector, thus eventuating his own death beneath the walls of Ilion, the citadel of Troy.

The *Odyssey* tells the story of the king and hero Odysseus and the trials he suffered on his way home from Troy, a ten-year journey. On his way home, Odysseus met with giants; Cyclopes; Sirens; the goddess Circe, who turned his crew into pigs; the goddess Calypso, who wanted to marry Odysseus; and the Phaiakians, a blessed population who lived at the edge of the civilized world. He even traveled to Hades to meet with the great prophet of Thebes, Tiresias. Arriving on Ithaca, his home island, Odysseus had to rid his palace of several dozen suitors who had been courting his wife Penelope and eating him out of house and home. Through all this, Odysseus had to rely on his wit and perseverance and on occasional help from his patron goddess, Athena.

THE EPIC CYCLE

The *Iliad* and *Odyssey* were only two, although apparently the best, of a series of epics recounting the lives of the gods and the events surrounding the Trojan War. Unfortunately, these other poems no longer exist and can only be vaguely reconstructed through references in other poems, such as the *Iliad* and *Odyssey*, and through commentaries written about them during the Hellenistic period and after. According to a quote preserved in the writings of Photius, the Epic Cycle dealt with everything from the marriage between Heaven and Earth through the death of Odysseus. Arranged chronologically according to subject, the first are the three Theban epics: the *Oedipodea*, the *Thebaid*, and the *Epigoni*. The *Oedipodea* was some 6,600 lines long and was attributed to a man named Kinaithon. It recounted the story of Oedipus (Oidipous), his murder of his father, and his ill-fated marriage to his mother. The *Thebaid*, possibly written by one Kallinos, told the tale of Oedipus's family, from Oedipus's curse on his sons Eteocles and Polyneices to the death of both in the Battle of the Seven against Thebes (referred to often in the Homeric epics). The city of Thebes is finally seized in the next generation according to the *Epigoni*, which Herodotus somewhat dubiously ascribed to Homer. The *Kypria*, composed by Stasinus, Hegesias, or possibly Hegesinos, tells in 11 books the story of the Trojan War before the events of the *Iliad*: the meeting of Helen and Paris,

their escape to Troy, and Menelaus's attempt to negotiate a return and settlement. In mythic time, the *Kypria* is followed by the *Iliad*, which itself is followed by the 5 books of the *Aithiopis*, ascribed to one Arctinus of Miletos. This poem deals with the final exploits of Achilles: his fight with the Amazon Penthesilea; his fight with Memnos, son of the dawn goddess; and his final death at the hands of Paris and Apollo. All of this is followed by Arctinus's second poem, the *Iliu Persis*, or *Sack of Troy*, in which the final days and eventual destruction of Ilion are recorded. An alternate version, attributed to Lesches or Kinaithon, is recorded in the so-called *Little Iliad*.

The *Odyssey* is but one narrative in the general collection of homecoming stories that took place after the fall of Troy. These tales are called Nostoi ("Homecomings") and were composed either by Homer or by Hagias from Troizen. The final poem in the Epic Cycle is the *Telegonia*, which is a continuation of the *Odyssey*. Part of this tale is foreshadowed in the *Odyssey*, when Odysseus must go on a final journey to placate the wrath of Poseidon. Odysseus is killed by Telegonos, his son with Circe (not mentioned in the *Odyssey*). In the end Penelope, Odysseus's widow, marries Telegonos, and Circe marries Telemachus, Odysseus's son with Penelope.

—Stephanie Lynn Budin

For years, the study of these epics focused on two problems: when were they composed and how. The question of when became especially acute once Schliemann discovered that places such as Troy and Mycenae actually existed, showing that the epics had some basis in historical fact. The problem was that although the epics seemed to be primarily Bronze Age in feel, some of the details were clearly from a later date. References to iron, for example, simply could not have originated in a strictly Bronze Age composition. However, many of the details, such as the importance of the "capital" city of Mycenae, not only were inaccurate after the Bronze Age, but they would have been unknown after the Dark Ages, by which time Mycenae was

little more than a shantytown with some old walls. When, then, could the stories have been composed so as to take into account cultural facts from so many periods?

Even before the issue of historicity arose, though, there was an interest in how the poems came into being. The Iron Age Greeks did not adopt a writing system until the eighth century (in fact, some people have suggested that writing was specifically adopted to record the Homeric epics). As at least some of the Homeric poetry derives from the Bronze Age and the Dark Ages, it is generally agreed that the poems were not originally written down but instead were composed and performed orally. How, then, could one individual remember so much

poetry off the top of his (or her) head? And was Homer one individual, a composite of several composers, or maybe the last in a long line of composers?

For a long time, the debate was dominated by two schools: the Unitarians and the Analysts. The Unitarians believed that the *Iliad* and the *Odyssey* were the work of one extremely gifted poet. The Analysts suggested that both were composed by several poets, only one of whom might be dubbed the mythic Homer. But in the early twentieth century, Milman Parry and Albert Lord conducted field research in one of the few closely related places where an oral epic tradition still thrived, Yugoslavia. Parry and Lord discovered that oral epic creation was a combined process of learning stories and memorizing formulae in the appropriate meter. So, the young would-be poet (usually someone who was illiterate and seldom a poet by trade) would spend several years of his or her youth listening to elders recite the great epics. From this, the poet would at least learn the tales, just as modern children learn about Cinderella and Peter Pan. But more importantly, the poet would learn what Parry and Lord called the formulae: groups of words, possibly even as long as entire lines, that were in the appropriate meter and that could be combined in various ways to narrate a story (much like the way limericks always seem to begin with “There once was a . . .”). What this means is that the poet did not have to memorize a poem verbatim (hardly possible, anyway, with the length of the poems in question). He or she merely learned the plot and then combined the formulae to tell the story in the appropriate poetic form. As such, there was no one standard form of any epic; in each recitation, the epic poem was created anew, an eternal re-creation.

This discovery answered many questions about the Homeric epics. The time range perceptible in the verses was attributed to changes that occurred in Greek society over the centuries when the epics were being re-created. The hypothesis of there being one single artist—Homer—was abandoned in favor of the Parry-Lord model, with possibly one fellow named Homer who popularized the tales just before they were written down.

This act of writing down crystallized the epics, that is, turned them from mutable oral poems into authoritative texts. Perhaps Homer dictated this finalized version, giving his name to epics that had been in existence for centuries before he was born. This writing down probably occurred in the eighth century BCE. Although there are several elements in the epics that clearly belong to the Bronze Age and the Dark Ages, many references seem appropriate for the dawn of the Archaic Age, and there is little in either poem that suggests a later date. Thus, although some have argued that the poems may have to be down-dated to as late as the sixth century, it is generally accepted that the *Iliad* and *Odyssey* began being written down somewhere between 750 and 700 BCE.

Prophecy in the Ancient Near East

Prophecy is a social phenomenon found around the world in which certain persons are understood to deliver messages on behalf of a deity or other extrahuman agents to other people. Commonly associated with predictions of future events, prophecy has also been used to disclose past events and the meaning of the past. The specific forms this practice takes vary widely from one culture to the next. Prophecy is also closely related to other practices, including divination and astrology. Prophecy, however, is typically understood as a more intuitive means of gaining special insights. This means that unlike the inductive practices that rely on the practitioner's skill or training in interpreting signs or omens in the natural world or random events,

prophets may receive messages through visionary experiences, dreams, or ecstatic experiences. One problem in understanding prophecy cross-culturally is that the ancient cultures had multiple terms and titles for the act of delivering divine messages and for those engaged in it. The English terms “prophecy” and “prophet” often enjoy only a partial correspondence to the diversity of ancient conceptions of how one might speak on behalf of the gods.

Although prophecy was probably widespread across the ancient Near East from 4000 to 1000 BCE, extensive written evidence of prophecy has survived from a relatively limited number of locales. There are two basic kinds of texts that provide information about prophets and their activities. A number of documents preserve actual oracles purportedly delivered by prophets, while other references to prophets and prophetic activity are made in writings such as letters, literary works, and administrative documents. It appears that much prophecy in the ancient world was an oral exercise, so recovering the actual words (the *ipsissima verba*) of the prophets from the oracular documents is not a straightforward procedure, as these texts may not be directly quoting the prophet.

The largest group of prophetic texts from this period in the ancient Near East are from Mari in present-day Syria on the west bank of the Euphrates River (modern Tell Hariri). Mari’s long history began before 4000 BCE, and the city enjoyed a second period of prosperity during the early second millennia BCE before being destroyed by Hammurabi in 1759 BCE. Among the approximately 25,000 clay tablets found in the city’s archives were some 50 letters reporting the words of prophets to the king and other kinds of material with references to prophets.

Some additional references to prophets appear in a wide variety of other documents as well. For instance, at about the same time as Zimri-Lim of Mari (ca. 1775–1761) was receiving reports of prophetic activity, the king of Eshnunna (northeast of Babylon) received two written oracles purportedly from the goddess Kititum (Ishtar). In the fourteenth century BCE a letter to Pharaoh Amenhotep III from the king of Mitanni (a region in present-day northern Syria)

quoted a prophetic oracle of Ishtar/Shauska, while in the next century prophets known as *munabbitu* are referred to in texts from Emar (modern Tell Meskene, Syria).

In the Mari documents, the most frequent label for someone whom modern people would call a prophet was *āpilum* or *āpiltum* (“answerer”). The vast majority of uses of the term identifies men and holders of the title as being of relatively high status. Another title was *mubhu/mubhum*, derived from a verb meaning “to go into a frenzy.” The evidence also suggests that the majority of these ecstasies were men, although not to the same degree as the answerers. Neither of these classes of people were priests, but they often functioned in the temple as spokespersons for a deity, often in response to queries by the king.

The prophets could speak for a variety of deities, including the gods Addu, Dagan, and Marduk and the goddesses Annunitum and Nin-hursagga. In a variety of guises the goddess Ishtar was very often involved in prophetic communications. One class of her spokespersons was the functionary known as the *assinnum* (“cult singers”), who also participated in ecstatic rituals.

There were other categories of prophets as well, although the evidence of their activities is sparse. A number of texts refer to the delivery of divine messages by people who are not given any formal title. In these latter cases, however, women outnumber men by a small margin. It is likely that other practitioners served people of lower social standing, but given that these activities were most probably exclusively oral, no record of them remains.

The prophets we can read about seem concerned with the relationship between political power and the divine. Many of the messages delivered by these prophets or reports of prophetic activity concern the outcome or dangers involved in upcoming situations such as war or diplomatic relations. A number of others concern proper practice of sacrifice and ritual, and some criticize the king for neglecting his religious responsibilities. A smaller number of the letters to the king of Mari report prophetic oracles delivered to a wider audience.

It is clear that prophets were taken seriously within the political and religious institutions of the day, although they were not of the highest status. The reliability of prophecy could be doubted, and so sometimes prophets and their pronouncements were subject to examination and confirmation of their reliability by other divinatory means (which themselves might be held suspect). Mari prophets would sometimes send a lock of their hair and a cutting from their clothing, which would then be the subjects of inquiry by extispicy, divination through examination of the entrails of sacrificed animals.

■ Introduction: Early Works of the Hebrew Bible

The Old Testament (or Hebrew Bible as it is also known) consists of a number of smaller works (usually called “books”) that were compiled well after 1000 BCE. Some of these books, however, were first written down in an earlier age. Other books within the Hebrew Bible purport to describe events that date to the time before 1000 BCE but were recorded later. Some of the books (or sections of books) are similar to literature and ideas that date to this period. The history of the composition of the Old Testament is a complex subject that is dealt with in more detail in later volumes. What is presented in the following entries are discussions of those parts of the Old Testament that were first written down before the end of this period.

Most of the early works of the Hebrew Bible are poetry or songs; the difference is difficult to identify in the absence of preserved music. Scholars are convinced of the antiquity of these sections of the Bible mostly based on the language used. The history of the Hebrew language is well understood. Subtle differences in the grammar, spelling, and word choice within the Bible help scholars to identify the original date of various sections. However, there is often much disagreement about individual sections or passages. What follows are examples that are usu-

ally taken to be the earliest parts of the Bible (although you will always be able to find scholars who disagree on the dates).

—Kevin M. McGeough

Early Biblical Oral Tradition

Early biblical oral tradition of the late second millennium BCE was an important means of preserving historical and cultural beliefs. It is possible to imagine a family around their home’s hearth or elders speaking at the gates of a city. The importance of oral tradition was not because there was a high level of illiteracy among average people. Many people possessed the ability to read, although it was likely limited to specific concerns such as business transaction and basic military reports. More complex reading and almost all writing would have been left to trained individuals, such as scribes or possibly religious leaders or members of the ruling class. When someone else required a learned ability to read or write, they would have hired someone who had been educated. Most stories and beliefs were much more likely to be passed on through a system of oral tradition.

One of the common misconceptions concerning oral tradition is that the transmission through communities would lead to changes in

ways that transmission through texts would prevent. However, the changes in retelling were likely limited to a culturally determined level of creativity and performance around a recognized tradition. Thus, when a parent told a child the story of Joshua, it may have changed based on the development of culturally normative ideas or the narrative style of the parent. The child would have learned the same narrative kernel that had been passed on from generation to generation. The preservation of central themes and narratives allowed oral tradition to be a relatively consistent form of transmission in a world without widespread writing.

A further scholarly question about oral tradition concerns what level of complexity could be preserved reliably. Early biblical scholars, such as Hermann Gunkel, theorized that oral tradition necessitated short, simple pieces to be effectively passed through cultures. When scholars looked back on texts to discover which would likely have originated in oral composition, they searched for sections representative of these theories. Since the work of William Foxwell Albright, this has been viewed as a misconception, underestimating the abilities of those dependent on oral traditions. Through this illumination scholars have recognized that many complex portions of the Old Testament text likely originated in oral traditions.

Without the general guideline of length, scholars were left with the question of what is indicative of an originally oral text. The clearest answer that has been offered is that texts of original oral composition present large amounts of repetition. This can be something as simple as the constant repetition of a word or phrase, as seen in the text of Genesis 1, verses 4, 10, 12, 18, 21, 25, and 31. Here, the text repeatedly refers to the acts of creation as being good. Such repetition would likely have been used by the original composer to emphasize a point. In this case, the composer was likely attempting to convey a positive nature to the acts of creation.

Beyond repeating words may be the repetition of quotations from an earlier work. This can be seen in Exodus 2:2, where a similar phrase to that used in the Genesis 1 creation narrative is used to label the pregnancy of Moses's mother as being good. Because the textual dating of Ex-

➤ REPETITION AS A MNEMONIC DEVICE?

Related to early scholarly theories that oral texts had to be simple to aid in memorization and retelling is the hypothesis that the repetition of words, phrases, quotations, and forms found in originally oral texts made them simpler and served as mnemonic devices. However, this idea has recently been seen as less important to other uses of repetition, as many have moved toward a model of oration that poses frequent reinterpretation of a basic story. The repeated nature of certain items may have been of greater use in quick oral composition than memorization of previous composition. The orator could easily compose a presentation of history each time by using common narrative conventions. A modern example might be ending a story with "and they lived happily ever after." It does not require great forethought for a person to pull this forth and fit it as an immediate conclusion. Just as these phrases would come easily to the orator, they would also be familiar to his or her audience. This would then allow them to link the orator's speech to other cultural ideals that they possessed. In the example of "and they lived happily ever after," many people would immediately be taken into the world of fairy tales and a specific type of culturally defined narrative.

—Thaddeus Jacob Nelson

odus 2:2 predates that of Genesis 1, it is likely that they both call to a common tradition in their authors' culture. Their shared repetition serves to link the Genesis 1 narrative and the conception of Moses to an antecedent cultural understanding of positive creation found in a preexisting tradition.

A final form of repetition to be concerned with is that of narrative patterns. An example of this can be found in the pattern of battle reports in 1 Samuel 4 and 2 Samuel 18. Both use a narrative form, giving information in the specific order: movement, military conflict, the battle's outcome, and the conclusion. In a manner similar to the repetition of words or quotes, the utilization of forms was likely meant to call on common understanding within the culture of the orator. In this case, listeners would have been

made aware that they were listening to the outcome of a battle.

Another example of oral tradition can be found in Joshua and Judges, books of the modern Old Testament that were written between 642 and 609 BCE but told of much earlier events. Modern scholarship has shown that the narratives they contain are anachronistic, telling about a much more glorious campaign of conquest than what historically occurred. This does not negate the accuracy of the narrative kernel as it was originally composed. Thus, as orator after orator presented the campaigns of Joshua and the Judges in a different time period, they adapted them to remain relevant. While doing so, they were able to maintain a central historical narrative that was in essence the same as in its first telling.

The Song of the Sea

The Song of the Sea (also sometimes called the Song of Moses or the Song of Miriam) is an old poem preserved in the pages of the Hebrew Bible (Exod. 15:1b–18) for which there is evidence that it reflects events from the twelfth century BCE and therefore may provide clues concerning the origin of the people of Israel and their appearance in the Levant.

The poem describes an encounter between the Egyptians and the people of Yahweh at the Suph Sea ("Reed Sea," commonly identified with the Red Sea). The Egyptians, armed with chariots and led by their pharaoh, are intent on attacking and destroying Yahweh's people and give chase. At the Suph Sea, Yahweh himself comes to the rescue and envelops the Egyptian army in the

waters and drowns them. Afterward, he leads his people to his sacred mountain, where his holy sanctuary is located.

Although not all scholars agree on the date of the poem, a substantial mass of evidence and argumentation has been assembled pointing to a very early date for its composition. The poem is written in archaic Hebrew (although later Hebrew forms are found in the poem as well) and likely predates the prose account of the same events in Exodus 14. Like the Song of Deborah, the Song of the Sea belongs to the genre of victory hymn, examples of which have survived from neighboring cultures, such as the Egyptian poems that celebrate the victories of Ramses II over the Hittites at Qadesh on the Orontes and of Merenptah over the Libyans and others as well as the Assyrian poem about Tukulti-Ninurta's triumphant campaign against the Kassites of Babylon. All three of these date to the thirteenth century BCE and are therefore somewhat older as well as much longer than the biblical examples.

One passage in the poem, which refers to the sanctuary of Yahweh in Yahweh's hereditary mountain, suggests to some interpreters that the poet had knowledge of the construction of Solomon's Temple on Mount Zion in Jerusalem. If true, the poem would have to be dated after circa 980 BCE, when the temple was built. However, others have argued that the mountain mentioned is in fact Sinai and that the poet imagines the sanctuary to be a heavenly temple built by Yahweh himself in the heavens above the mountain. Since the trek to the mountain appears to follow immediately after the defeat of the Egyptian forces at the Suph Sea, it seems best to understand the mountain as Sinai. Other than this passage, the poem reflects no knowledge of a later period. There is no mention or presumption of an entry into and settlement of Canaan. In other words, the scope of Exodus 15 appears to be limited to the victory at the Suph Sea and its immediate consequences: the march through the wilderness and the settlement at the holy mountain there.

Another passage having a bearing on the date of this poem is to be found in verses 14–15. The verse lists four peoples shocked at the news of the Egyptian disaster: Philistia, Edom, Moab, and Canaan. From a historical and chronological

point of view, there is only one period during which these four peoples coexisted in the area from the border of Egypt to the northern perimeter of Palestine somewhere between 1175 and 1100 BCE.

If this dating is correct, then the encounter with Egypt mentioned in the Song of the Sea would have occurred after Egyptian pharaoh Merenptah boasted of a victory over the people of Israel in a stele he erected in 1207 BCE. Some may see a problem with this interpretation, since it is assumed that the Song of the Sea recounts events associated with the Israelite exodus from Egypt, and they cannot envision any Israelites in Canaan prior to that exodus. To them, any exodus would have to precede the time of Merenptah. However, there is no reason to assume that the people referred to in the Song of the Sea are the same Israel that Merenptah refers to in his stele. Israel is not even mentioned in the Song of the Sea; the community pictured in the poem is simply called Yahweh's people. This movement is described as a new society that came into existence at the revelation of their God Yahweh at his sacred mountain. Ultimately this new community found a permanent home in Canaan and would have become an integral component, if not the central component, in the tribal league of Israel, but they may not have been part of this confederacy at the time of the events recounted in the poem. Indeed, as there are only ten tribes mentioned in the Song of Deborah, it would seem as if there were other tribes yet to join the league. These may be the tribes associated with the exodus and the Song of the Sea.

THE SONG OF THE SEA—AN EXCERPT (VV. 3–10)

"Yahweh is a warrior; Yahweh is his name.
Pharaoh's chariots and his army he cast into the sea,
And his elite officers sank in the Suph Sea.
The Deep covered them;
They went down into the depths like a stone.
By your right hand, Yahweh, resplendent among the mighty.
By your right hand, Yahweh, you shattered the enemy.
By your great superiority you threw down your antagonists;
You sent forth your anger, which devoured them like stubble;
By the blast of your nostrils the waters were heaped up,
The waves mounted as a bank,
The Deep congealed in the heart of the sea.
The enemy boasted, 'I'll pursue; I'll overtake, I'll seize the booty; my gullet will be filled with them;
'I'll bare my sword; my hand will dispossess them.'
You blew with your nostrils—the sea covered them;
They sank like lead in the dreadful waters."

The Song of Deborah

The Song of Deborah is the common name for an ancient Hebrew poem now found in the fifth chapter of the biblical book of Judges. The poem is of interest to historians because it appears to be quite old, older in fact than the prose surrounding it, and may provide some clues about

► THE SONG OF DEBORAH— AN EXCERPT (VV. 19–22)

“Kings came, they fought,
At that time, they fought, the kings of Canaan,
In Taanach, near the waters of Megiddo
But spoils of silver they did not take.
From the skies the stars fought,
From their courses they fought against Sisera.
The torrent Kishon swept them away,
The torrent attacked them, the torrent Kishon.
(May you press down the necks of the powerful!)
Then the hoofs of the horses clattered,
From the charges of the charging steeds.”
(Judg. 5:19–22)

Translated by David Miano

the history of the people of Israel in the early Iron Age.

Regarding the date of the poem, its language appears to be quite archaic. There are several forms and elements within the poem that are examples of Hebrew usage prior to circa 1000 BCE. To be sure, some scholars have taken issue with this observation, arguing that the original author of the poem deliberately archaized the Hebrew to give it an authentic feel. However, it is unlikely that later writers would have knowledge of some of the older forms we find in the poem. There are later Hebrew forms in the poem as well, but these are more likely to be later unconscious updates by scribes than original readings.

The poem is a victory hymn. The setting of the poem is the period before the Israelite monarchy (thus before ca. 1000 BCE), and in it is recounted a battle between the tribes of Israel and the Canaanites near the city of Taanach, as a result of which the Israelites brought to an end Canaanite political hegemony and military superiority in the land. The battle, if it is historical, likely took place in the mid- to late twelfth century BCE, after the Egyptian empire had lost control of the area but when the Canaanites still held sway over the land. Archaeology has indicated that significant sections of the city of Taanach were destroyed in about 1125 BCE. The poem was written no more than a century or two after

the battle and most likely immediately after it, if we can take the other victory hymns of this period as parallel.

The Israelite campaign appears to have been prompted by an economic crisis. There are indications in the poem (verses 6–8) that the Israelite tribes were profiting from trade through the hill country and across the Jezreel Valley. Sisera and the Canaanite allies were stifling the caravan traffic through the plain, and this was having a detrimental effect on the Israelite economy. The tribes went on the offensive to protect their economic interests.

The poet attributes the defeat of the enemy not to the superior might of the Israelite armies (they were in no way superior) but rather to forces of nature (i.e., divine intervention). The stars of the skies fight in the battle, and the kings of Canaan are said to have been swept away by the river Kishon. This may indicate that the battle was waged during a storm. The image is reminiscent of the conflict recounted in the Song of the Sea in which the chariots of Pharaoh are sunk in the Suph Sea.

The central section of the Song of Deborah describes the mustering of the tribes or political units for the battle. All indications are that the units listed in the roll call were expected to supply troops for the engagement. Some participated, and others did not. Noteworthy is that there are only ten names. Several tribal names that appear in the more traditional lists elsewhere in the Bible are absent here. The tribes known more commonly as Manasseh and Gad are likely to be associated with the names Machir and Gilead in the poem. More significantly, Simeon, Levi, and Judah do not appear at all in the poem. A common explanation is that these southern tribes were cut off from the others by a line of fortified Canaanite city-states and thus did not merit mention here. However, it is important to note that tribes that did not take an active part in the struggle (Reuben, Gilead, Dan, and Asher) are listed along with those that did. This means that the list does not derive from the circumstances of the battle but rather reflects an already-existing organization, that is, a confederation of some kind united under the name “Israel.” It therefore is best to suppose that at the time of the battle (or at the time of composition),

the southern tribes were not a part of the Israelite tribal confederacy.

An interesting feature that separates the Song of Deborah from many of the other early poems of the Bible (e.g., Num. 23–24, Gen. 49, Deut. 33, 2 Sam. 23, and Ps. 78) is that the name “Israel” does not appear alongside of, or in parallel with, the name “Jacob.” Instead we find the expression *‘am Yahweh* (“Yahweh’s people”). In the later days of the monarchy, there was a distinctive correlation between the name “Israel” and the ten northern tribes. That correspondence is fully attested at the time of the divided kingdoms, when the northern group of ten tribes separated from the dynasty of David to establish its own realm under the name “Israel” (see 1 Kings 11:26–39, esp. vv. 30–32, 35–36). That this move was a restoration, rather than an innovation, is confirmed by the fact that after Saul’s death, his son Ishbaal was crowned king only of Israel (2 Sam. 2:8–9), while David became king of Judah at Hebron (2 Sam. 2:1–4; cf. also 2 Sam. 19:41–44). It thus is not that surprising to see the ten northern tribes called “Israel” in the poem. These data also imply a relationship between the southern tribes and the name “Jacob,” both of which are absent from this poem. Thus, the distinction between the northern and southern confederacies appear to go back to the time of the Song of Deborah (or even before).

Early Ancient Israelite Poetry before 900 BCE

Assigning composition dates to any biblical psalm is a difficult task. This is largely due to the poetic nature of the psalms, as poetry is more difficult to date than prose texts. Generally, when composition dates are assigned to prose texts, scholars examine the vocabulary, orthography (or spelling), and grammar of the text. Just as English has changed over time, with the disuse of words (“thou/thee/thy”) and of grammatical forms (“doeth/does”), the language of the Bible also changed. Poems containing older forms are considered archaic, although, as in modern English, a biblical poet could intentionally use older words and grammar to elevate his rhetorical style, a process known as archaizing. However, archaizing poets often misunderstand the old grammar and vocabulary, leaving cues as to the poem’s later date. Such cues are not always identifiable, however, as a later copyist might alter an older text to conform to the grammar or orthographic practices of his own day, leaving behind only a bare residue of the archaic forms. The biblical scholar must then attempt to determine which aspects of a seemingly archaic poem have been intentionally archaized by poets and then modernized by scribes. The poetry from the book of Amos (ca. eighth century BCE) offers one useful standard against which to compare archaic grammatical and orthographic differences in such determinations.

About a dozen poems are routinely accepted as examples of early Hebrew poetry with composition dates preceding the divided monarchy (ca. 920 BCE). Of these, the Song of the Sea (Exod. 15) and the Song of Deborah (Judg. 5) likely date to the twelfth century BCE. The Song of Moses (Deut. 32) and the Royal Psalm of Thanksgiving (2 Sam. 22 = Ps. 18) likely date to the eleventh century BCE. The Blessings of Jacob (Gen. 49), the Balaam Oracles (Num. 23–24), the Blessing of Moses (Deut. 33), and the Song of Hannah (1 Sam. 2) may also date to the eleventh century BCE, but because they exhibit fewer archaic forms, such early dates are less reliably

▶ PSALM 29

Ascribed to David, this psalm portrays the Israelite god Yahweh as a storm-god. Yahweh thunders over the waters, breaking cedars and stripping oaks in a manner characteristic of the Canaanite storm-god Baal. In 1935, H. L. Ginsberg published five proofs claiming that the psalm was originally a Canaanite song of praise to Baal and was only later adapted to Yahweh by Israelites. Indeed, later scholars even suggested that “Yahweh” was simply inserted into a Baal hymn in a cut-and-replace fashion. Among these proofs were the pagan elements referring to the “sons of gods” (v. 1), the praising of “God’s voice” (vv. 3–9), the geographic names from Lebanon (vv. 6, 8), the enclitic *mem* (v. 6), and the so-called climatic parallelism (vv. 1–2). Later scholars suggested several additional proofs. Ginsberg’s article was heavily influenced by the discovery at Ras Shamra in 1929 of the Ugaritic language, a second-millennium Canaanite language. Undoubtedly, Psalm 29 contains themes, motifs, and grammar common to Canaanite and Ugaritic myths about Baal; however, further investigations have also found these elements elsewhere in the Bible. Thus, the resemblances between Psalm 29 and the Canaanite poetry reflect the common heritage of the Israelites and the Canaanites. The archaic enclitic “mem” suffix and the climatic parallelism, however, which are found in the oldest Hebrew poems in Exodus 15, do suggest an early date for this poem, potentially as early as the united Israelite kingdom.

—*Spencer L. Allen*

attributed to them. Thus, both the Blessing of Jacob and the Blessing of Moses likely consist of ancient sayings that had existed in oral form but were only compiled and transcribed in later periods. A third group, dating to the tenth century BCE, includes three psalms written by King David: David’s Lament (2 Sam. 1), the Oracle of David (2 Sam. 23), and the Royal Psalm of Thanksgiving (2 Sam. 22 = Ps. 18). Psalms 78, 68, and 72 are, respectively, attributed to David, Asaph, and Solomon by the superscripts and may date to the tenth century BCE, although a ninth-century BCE date is also possible. Finally, there are several poems embedded within other passages that also display early Hebrew characteristics. These

include Habakkuk 3, Psalm 74:13–17, Psalm 77:14–21, Psalm 89:6–15, and Psalm 92:9–10.

Indeed, all but 24 psalms begin with a superscription. These include 73 that are associated with David, of which 13 explicitly relate the psalm to a moment in David’s life (as in Ps. 51:1). Twelve superscriptions are associated with Asaph, a contemporary of David, and one each with Solomon and Moses. Although usually translated into English as “a psalm of David,” the precise meaning is obscure and likely is not meant to signify authorship. Therefore, these superscriptions alone should not be used as a criterion for dating psalms. The superscriptions’ lack of reliability is demonstrated by the differences between the Hebrew and Greek textual traditions. Psalm 29, which has a superscription associating it with David, does display archaic tendencies and may even predate King David by as many as 200 years.

That the earliest poems are located in the Pentateuch and the historical books rather than the book of Psalms reflects their relative religious importance. The content and status of the Pentateuch and historical books were secured as scripture and canonized well before the unit containing the book of Psalms. By the time the psalms were canonized, a long and multistaged process, there was little reason to add the earliest, already canonized poems to the collections that would become the book of Psalms. One notable exception is the Royal Psalm of Thanksgiving, which is found in both 2 Samuel 22 and Psalm 18, with the two chapters actually reflecting two variant traditions. The version in 2 Samuel 22 was composed in the northern kingdom of Israel, while Psalm 18 was composed in the kingdom of Judah. The grammatical and orthographic differences between the two versions are indicative of the dialectal differences between Israel and Judah and, more importantly, allow scholars to identify the poem’s archaic characteristics. For instance, the orthography of 2 Samuel 22 reflects the contracted diphthongs common to Israelite and Phoenician pronunciation of the ninth and eighth centuries BCE. These contractions, in which *ay* is shortened to *ê* and *aw* is shortened to *ô*, are indicated by the lack of the letters *yodh* and *waw* in the spellings. In contrast, the Judahite dialect of this time retained

the diphthongs, so *yodh* and *waw* appear in the spellings as expected in Psalm 18. As these different spellings are attested numerous times between the versions, they likely represent actual ancient traditions, in this case dating to no later than the eighth century BCE rather than modernizations by copyists. A second archaic feature is the presence of the so-called enclitic *mem*, a suffix indicating emphasis. The enclitic *mem* is common in the language of Ugarit (ca. 1400–1200 BCE), an older sister language of Hebrew, but grew increasingly less common as biblical Hebrew developed. The Hebrew text in 2 Samuel 22:16 is *'pq ym* (“sea channels”), while the Hebrew in Psalm 18:16 has *'pq mym* (“water channels”). Note the extra “m” in the latter. Likely, a scribe transposed the first “m,” thus changing *'pqm ym* to *'pq mym* because he no longer understood the value of the archaic enclitic *mem*. Finally, a change in the meaning of certain words can be seen between these two versions. The preposition “b” in Psalm 18:14 has the meaning “from” instead of the common meaning “in/on.” This meaning is unexpected

for the biblical Hebrew preposition, although it takes both meanings equally well in Ugaritic. The parallel preposition in 2 Samuel 22:16 is *min*, the expected Hebrew word for “from,” again highlighting both the scribal practice of modernization and the archaic forms underlying these changes in the two versions of the Royal Song of Thanksgiving.

■ Introduction: Vedic Religion

From about 1800 to 1400 BCE (although the exact dates are heavily debated), Vedic society emerged in India. Although the relationship between Vedic society (or Aryan society, as it is also called) and the Indus Valley civilization is contested, by 1200 BCE Vedic culture was predominant in the Indian subcontinent. Although not politically united, Vedic society shared a common ethnic identity and many other cultural traits. Vedic religion was one of these common features, and many of the elements of early Vedic religion are still important in Hinduism today. Sometime between 1200 and 800 BCE, the oral traditions of Vedic religion were written down in Sanskrit into collections of religious poetry known as Vedas. What follows is a discussion of this Vedic literature along with discussion of some of the main themes of early Vedic religion.

—Kevin M. McGeough

Vedic Cult and Rituals

The religious and ritual cult operative within the Vedic literary corpus, though referred to as early as the Rig-Veda, reaches its creative apex only several centuries later in the ensuing Brahmana ritual texts. This mode of ritual focuses primarily on the element of fire and its successful maintenance, a similar cult also having been practiced among the Parsi communities in South Asia since the time of the composition of their own sacred text, the Zend Avesta.

The Vedic fire cult has two primary, and interrelated, manifestations: the solemn (*sbrauta*) rites and the domestic (*grihya*) rites. Whereas the domestic rites focus on a single fire that is to be kept continually burning—or at least smoldering—inside the house, the solemn rites require the generation and maintenance, for the duration of a particular ritual, of three fires within a separate

► THE HORSE SACRIFICE

One of the most interesting and controversial of all Vedic rituals was the royal horse sacrifice (*asvamedha*). This is one of several festivals performed only by the king, and its successful performance led not only to increased fame for the king but also to additional land and income for his kingdom. The king and his priests would send a consecrated horse, accompanied by an army, around the borders of the kingdom; should the horse travel into the territories of neighboring kingdoms, its kings would be obligated to pay tribute to their new master. The alternative outcome was, of course, a pitched battle. Following the horse's successful return to the city, he would be sacrificed and his body cleansed. The king's three wives, who had regular duties in all standard animal sacrifices, then would decorate the dead horse with auspicious objects (e.g., gold and silver coins). The texts finally prescribe (although the early Western translators often omitted this section or even translated it into Latin) that the king's chief wife, in order to most fully imbibe the essence (*medha*) of the horse (*asva*), is to lay down with the deceased horse to the accompaniment of bawdy songs, jokes, and dancing.

—Michael Baltutis

enclosure (*vihara*). The circular western fire is called the *garhapatya* (the lord of the house), and it is generated in one of two different ways: it is either taken directly from the previously existing single domestic fire, or it is produced by drilling with two pieces of wood. In order for an individual to be qualified to establish the fires (he is called an *abhitagni*), it is required that he be married; during the performance of the Vedic rites, his wife will be seated to the southwest of this western fire with her face turned toward the northeast. Many of the ritual preparations will occur here. The semicircular *dakshinagni* (southern fire) is in the south, and this fire is to be taken from the house of a rich man and is the recipient of offerings to the ancestors. The square *abhavaniya* (offering fire) is placed in the east; its fire is to be taken in a vessel directly from the western fire, and the majority of the offerings made during the course of any Vedic rite

are placed into this fire. Placed in the center of these three fires is a central space (*vedi*) that runs from west to east and is measured to correspond precisely to the height of the sacrificer. The *vedi* is both the place where many of the ritual implements are kept and the place the gods are invited to inhabit for the duration of the ritual.

Each rite requires the involvement of three elements: a particular deity, chant, and offering material (*devata*, *mantra*, and *dravya*). The content of these three elements not only distinguishes one ritual from another, but the common process of the replacement of one particular deity, chant, or material for another allows for significant flexibility and variation within the particular ritual framework. Thus, the texts not only allow for the replacement of *soma*, the intoxicating, inspiring, and rare substance consumed by the priests, but even the milk offered in the twice-daily *agnihotra* rite has its own list of substitutes, listed in decreasing order of desirability: rice and barley, herbs, fruit, and water. The deities and Sanskrit-language chants employed in the Vedic cult are extraordinarily numerous. While the *agnihotra*, the simplest of all Vedic rites, employs only one priest who recites mantras from only one of the Vedas (the Yajur Veda) and only Agni, the god of fire, receives this offering, all other and more complex rites will utilize priests who will chant mantras from all of the Vedas, and multiple deities and groups of deities will benefit as the recipients.

A sacrificer's ritual career begins with his marriage and the ensuing establishment of his domestic fire and ends with his death, when his ritual implements are burned along with him on his funeral pyre. The Vedic cult, being a predominantly calendrical one, is composed of a set of rituals that marks off the series of chronological junctions (*parvan*) throughout the lifetime of the sacrificer: days and nights, half-months, seasons, half-years and years. These junctions are traditionally seen as dangerous times, moments that sit between established units of time. As the intervals of time grow larger, so also do these rituals grow more complex: in addition to an increase in the number of priests required for each, the fundamental category of rite also changes, requiring the offering of a different substance.

The Vedic cult functions to maintain ultimate continuity in spite of these junctions, and it is supported by the myth of the reconstitution or perfection of a cosmological whole that has become flawed (the body of the god Prajapati) using the medicine of earthly ritual (via the body of the properly initiated sacrificer).

The Vedic ritual cult is composed of three categories of ritual, although the daily agnihotra rite, which requires the offering only of milk and also possesses a domestic (*grihya*) counterpart, is considered a *havir-yajna* (sacrifice) and sits outside this traditional system. The first of the three ritual categories is the *ishtī* (offering), whose prototypical rite is the twice-monthly full- and new-moon offerings. These rites, along with the agnihotra, are the only ones whose performance is said to be necessary for all ahitagni. Unique in these rites are the baking of bread, which is offered to the gods on a number of potsherds, and the offerings made to the ancestors on the southern fire during the new-moon rites. The three agriculturally oriented four-monthly rites (*caturmasya*) closely follow the full- and new-moon rituals, though employing five priests.

While the second category, the semiannual animal sacrifice (*pashubandha*) that adds a sixth priest, may be performed as one piece of the larger soma rite (the third category of Vedic ritual), it also constitutes its own independent rite. Although an animal is sacrificed in this rite, there is a high degree of ambivalence toward the taking of the animal's life. The animal is initially tied to a wooden post that is placed exactly on the eastern border of the ritual space, thus half inside and half outside. The animal is then led to and killed in a place outside the ritual space, and the priest who is responsible for the killing is a minor figure who must kill the animal by strangulation without shedding any blood.

The final ritual category is the annual soma sacrifice (*agnistoma*), which requires the fullest possible complement of 16 priests and involves the gathering, transportation, purchasing, preparation, and consumption of the soma drink by each of the priests, who each possess a uniquely formed wooden cup from which they drink. While it is required that ritual fees (*dakshina*) are given by the sacrificer to the priests of all the

aforementioned rites, those given for the agnistoma are the highest and can include 1,000 cows or even the sacrificer's daughter.

Vedic Priesthood

The priesthood required to perform the set of rituals commonly categorized as Vedic ritual (*yajna*) was intimately tied to this set of religious procedures. Therefore, with the historical shift of religious performance away from Vedic ritual and toward what has become contemporary Hindu temple worship, a style of performance that requires at the most a single officiating priest, the fate of this priesthood was sealed.

From as early as the text of the Rig-Veda (ca. 1800 BCE), we begin to see references to the names and functions of the priests (*ritvij*) who would eventually form a cohesive though variable group in the ensuing genre of the ritually oriented Brahmana texts. There are two main categories of Vedic rites, one solemn (*shrauta*) and the other domestic (*grihya*). In addition to the differences in location at which these rites are performed (in public and at home, respectively) and the number of fires required (three and one), each of these two types requires a priesthood that varies both in number and identity. For the domestic rites, only one priest is required—the *adhvaryu*, about whom more will be said below—although some texts allow for the householding and sponsoring ritualist (*yajamana*) himself to act as the priest. The numerical variability of and within the shrauta rites follows directly from the type of ritual that is being performed. Due to the relative lack of requisite priesthood in the domestic ritual, the often extensive priesthood required in the shrauta rites will be discussed.

➤ MAGICAL SPELLS IN THE ATHARVA VEDA

While the language of the Atharva Veda is just as archaic as that of the Rig-Veda, its status in this early period is still unclear. It was not until several centuries later that this text, which is so closely associated with the *brahmana* priest, attained an orthodox status. One reason for this delay is simply the content of the Atharva Veda. Instead of providing sacred hymns or instructions for the *shruta* ritual, it contains a variety of charms and spells. One section of the text includes hymns that protect its user from fever, jaundice, and constipation, while other hymns ensured long life, the obtaining of a good wife, and the birth of a son. Hymns specifically for use by women are also present, including those that prevent miscarriage and those that arouse the love of a man. And there were also special spells for kings whose goals included the assurance of his successful rule and his restoration to the throne if he were deposed.

—Michael Baltutis

The Vedic priesthood is structurally based on the textual corpus of the Vedas. Although eventually this canon came to include four Vedas, it was originally only the first three—Rig, Yajur, and Sama, representing the triple wisdom (*trayi-veda*)—that supplied a set of priests: one primary priest and a coterie of three assistants from each. A fourth and overarching main priest was present, however, and with his three assistants and with the occasional attendance of one additional and mainly honorary member (*sadasya*), a maximum of 17 priests could be present at some of the more major Vedic rites. But this was quite rare.

Vedic ritual is calendrical, and the less frequent the performance the more extensive is the priesthood. Thus, for the daily offering (*agnihotra*), just as for the daily domestic rite, only one priest may be required. This priest is the *adhvaryu*, the priest from the Yajur Veda, the text most concerned with ritual performance. The cumulative effect of Vedic ritual requires the presence of the *adhvaryu* at all subsequent rites. The semimonthly new- and full-moon rites (*darsha-purna-masa*) add the *bota*, the priest of the Rig-Veda; the *brahmana*; and the *agnidbra*,

an assistant of the *brahmana*. Three times each year, one of the four-monthly seasonal rituals (*catur-masya*) was celebrated; these performances added the *prati-prasthata*, the assistant and double of the *adhvaryu*. The semiannual animal sacrifice (*pasubandha*) added the *maitra-varuna*, a Rig Vedic assistant. And the annual Soma offering (*agnistoma*) required the full complement of 16 priests.

The jobs of each of these priests are clearly delineated according to their textual associations. Thus the *adhvaryu* and his assistants, seated near the eastern *abhavaniya* fire where most of the ritual substances are offered, are responsible for the majority of ritual performances; the *bota*'s job is to chant mantras from the Rig-Veda; and the *udgata* is to sing songs from the Sama Veda, though he is present only at the annual Soma rite. For performing their priestly duties, all of the priests will receive a gift (*dakshina*), preferably of either cows or of gold.

The *brahmana*, who was mentioned above and who is nominally associated with the Atharva Veda, the fourth of the four Vedas, served as the doctor of the ritual and is responsible for ensuring that each priest correctly performs his duties. This means, of course, that must he be fluent not only with the content of the Atharva Veda, even though this text was not often used in these rites, but also with the content of the three other Vedas, for which the three main priests are responsible. This comprehensive knowledge granted him a position that was at once the highest within the priestly hierarchy yet also one that was somewhat outside of it completely due to his lack of relevant textual affiliation and relatively inactive role within the rites. But his extensive knowledge granted him the power to assign expiation (*prayascitta*) to all of the priests for inevitable ritual mistakes. While lists of such mistakes run into the thousands and include many that were rarely if ever made, an example of one of the more practical expiations would be the purifying of the wooden drills used to create fire should they become defiled through contact with an unclean object (such as a crow or a dog). On the other hand, since his primary duty is to remain silent throughout the proceedings, it has been said that his

function was merely to maintain the structural continuity of the ritual while the other priests were inactive.

There are additional ritual officiants present throughout the more complex Vedic rites who are not deemed to be priests. Two of these ancillary priests appear in the rite of the animal sacrifice (*pasubandha*). The carpenter (*takshan*) is responsible for fashioning the wooden stake to which the sacrificial animal is temporarily attached. And the *shamita* (“the pacifier”) is responsible for the bloodless sacrifice, usually strangulation, of the animal.

Throughout later Vedic and post-Vedic texts, the brahmana priest, with his purported (if not real) knowledge of all three Vedas and also with his knowledge of Atharva Vedic rites specific to kingship, was granted a royal position in the king’s court. This priest, the king’s domestic purohita, appears frequently in the Sanskrit epics as the king’s personal priest who performs rites ensuring the king’s success in battle or the successful continuation of the king’s lineage. Within descriptions of popular festivals, the authors’ frequent emphasis on the activities of the purohita and the king (e.g., the recitation of mantras) has the effect of shifting the focus of the text from the contemporary and the common to the ancient and the Vedic.

Vedic Worldview

Any description of a Vedic worldview is necessarily limited by the texts available to us. The ritually oriented Vedic canon was composed by a related though not monolithic group of literate high-caste Brahmins who never specifically posited anything like a worldview—or any other doctrine, for that matter—in their texts. Thus,

elements that would comprise a tradition’s coherent worldview—origins, ethics, cosmology—are somewhat scattered throughout the ritual and mythic details contained in these texts.

Generally speaking, there are three types of myths in the Rig-Veda: myths of sovereignty, of war, and of reproduction. Thus, the Vedic worldview can be said to be more immanent than transcendent: while concerned to some degree with a life after death, the early Vedic authors and ritualists placed more emphasis on earthly success in regard to kingship, victory in battle, and the procreation of children. The Vedic emphasis on battle and victory, themes that permeate much of the Vedic cult, focus on one particular and apparently historical battle, the so-called Battle of the Ten Kings. This battle, led by the warrior-king Sudas, solidified the Aryan jurisdiction over northwestern India, established Indra as the primary Vedic deity, and allowed for their migration throughout the whole of northern India. Later stories and epic tales modify this original story to narrate the victories of other clans and of the victory of the gods over their demonic adversaries. The Rig-Veda also possesses hymns that could be described as naturalistic (e.g., a hymn of praise to Parjanya, the god of rains) and others concerned with magic (e.g., a hymn in which Indra uses the ritually important plant soma to cause crops to grow).

The Vedic worldview includes no single creator of the world; rather, different passages provide different deities with different creative functions. The dual divinity Dyaus-Prithivi—the male Sky and female Earth—are most frequently said to account for the creation of the universe, but they are not creators in the traditional sense of the word. In the later Brahmana texts, Prajapati (the lord of creatures) is the creator who is identified with both the year and, like Vishnu, with the sacrifice itself. Visvakarman (he who creates all) and Tvashtri (the fashioner) are also deities who create, yet their creations are typically limited to the weapons of the gods and the ritual implements of the priests.

The structure of the Vedic universe represents one of the most consistent components of the Vedic worldview. It is composed of three distinct portions—earth, the middle atmosphere, and the sky (*bhumi*, *antariksha*, and *svarga*)—

➤ ANCESTOR VENERATION

In the Vedic ritual calendar, following the single day, the half-month was the basic unit of time: the auspicious bright half concluded with the full moon, and the inauspicious dark half concluded with the new moon. The dark half of the month, and especially the day of the new moon, was defined by the worship of the ancestors (*pitar*), a practice that continues in South Asia today. Vedic ritual texts prescribe the monthly worship of the ancestors of the three preceding generations—father, grandfather, and great-grandfather—on this day with the production of three rice balls (*pinda*). The sacrificer, wearing his sacred thread over his right shoulder rather than the usual left shoulder—cooks the rice, feeds the middle ball to his wife in order that she will produce a heroic son, and disposes of the other two in either water or fire. At the end of this ritual, the ancestors are requested to depart to heaven after bestowing wealth and welfare upon the sacrificer and his family.

—Michael Baltutis

and is sometimes said to be supported by bolts or ropes. Each portion is populated with its own set of divinities, led by Agni (the sacrificial fire), Indra (the god of storms and warriors), and Vayu (the wind), respectively. The earth is also populated by humans, the descendants of Manu, the original man, and the seven primordial *rishi* (sages). Also said to be the first ancestor of all humans is Yama, who early on additionally becomes the god of the dead. While this three-part system does not include a heaven or hell—earth is the lowest of the three places—a full and successful life is rewarded with eternal life in *svarga* (the sky), the place of all the ancestors.

Prayer and sacrifice are the two primary means of propitiating the gods, and it is these religious performances that serve as the very foundation of the Vedic worldview. While it is not the case that every Vedic hymn is used in one or another ritual, as some early Western scholars had thought, it is the words (*mantra*) themselves, whether alone or in the context of a ritual, that are effective. In order for humans to

receive worldly benefits from the gods, they must shower the gods, who have the priests as their earthly manifestations, with praise and material offerings. And these offerings, when made in the context of a ritual and when equated with the constituent components of the universe, have the ability to correct and re-create the inherently imperfect world.

The definition of a full and successful life is defined not by a strict ethical system—such a thing is not worked out in the Vedic texts—but the individual is said to be born with four debts (*rina*) to four different entities, and each must be paid off in its own way. One's debt to the gods is paid off through the proper performance of Vedic ritual: that to the ancestors with sufficient progeny, that to the *rishi* with the study of the Vedas, and that to fellow humans with proper hospitality. Vedic and post-Vedic texts are replete with tales of kings, warriors, *rishi*, and gods fulfilling each of these four debts, of the faithfulness with which they perform them, and of the obstacles that demonic enemies create in order to prevent their proper performance.

Though it is assumed that the concept of history is not a significant element within Vedic literature, it is evident that the Vedic authors had exerted some effort in relating certain events with an aura of historicity. The Battle of the Ten Kings is related in several different books of the Rig-Veda and thus by authors from several different families, and the actions of the participating kings and warriors reads, at some points, like a narrative account of the battles. The Vedic concept of history is, on the other hand, often placed in cosmological terms likening one's own side to the gods and the enemy's side to the demons. The establishing of family lineages and textual schools represents another important example of the Vedic notion of history.

Vedic Literature

The term Veda derives from the Sanskrit root *vid*, meaning “to know,” and constitutes a body of wisdom revered by the Indo-Aryans, the people to whom it belonged. Even today, among all their varied scriptures, orthodox Hindus who claim to be of Aryan descent hold the highest regard for Vedic literature, which espouses Indo-Aryan beliefs and values. The language of this literature is Vedic Sanskrit, an ancient form of Sanskrit related to Avestan, an archaic form of Iranian, both of which belong to the Indo-Iranian subgroup of Indo-European languages. The term “Vedic literature” is ambiguous, although it is mostly used to refer to four textual types: the Samhitas, Brahmanas, Aranyakas, and Upanishads. However, it may also include supplementary works, collectively labeled the Vedangas, or “appendages of the Vedas.” Since the category of Veda carries substantial religious prestige, it is not unusual to see other texts broadly designated as part of the Vedic corpus, sometimes as Upangas (“secondary appendages”), or merely included in lists of Vedic literature, because they are deemed to resonate with the culture of orthodoxy associated with Vedic teachings. However, apart from the Samhitas, Brahmanas, Aranyakas, and Upanishads, which are regarded as *shruti*, all other literature is classified as *smriti* (from *smri*, “to remember”), namely, teachings that have been composed by human beings and passed down through generations as “tradition.” In contrast, shruti literature is believed to have not been authored by human beings but divinely perceived and chanted (*sru*, “to hear”) by semi-divine seers (*rishi*). Although this literature was eventually committed to writing, it was originally a completely oral textual tradition whose procedures of memorization and recitation still endure among select families of the priestly class known as Brahmins (*brahmana*). While the shruti literature is certainly religious in its content, even the peripheral works, which include topics such as grammar and medicine, could arguably be considered religious, since they are said to be forms of knowledge necessary for the cultivation of members of the priestly class and the proper performance of their duties.

The Samhitas

The oldest text in the corpus of Vedic literature is the Rig-Veda Samhita, a collection (*sambhita*) of 1028 hymns (*rig*, meaning “verse”) of praise, mostly to deified aspects of the natural world, such as Fire (Agni). These hymns are divided into ten books, or *mandalas*. The first and last mandalas are acknowledged as being compiled later than the inner core containing the family books attributed to the lineages of particular patriarchal seers (*rishi*), who are believed to have intuitively received the divine compositions. Book nine is dedicated entirely to Soma, a deified plant and the intoxicating beverage extracted from it, that played a central role in Vedic religious rituals. It has been difficult for scholars to pinpoint when the hymns of the Rig-Veda (RV) were composed and when the collection was compiled. Cuneiform Hittite-Mitanni treaty tablets discovered at Boghazkoy (in Cappadocia in modern Turkey) from about 1400 BCE mention the gods Mitra, Indra, and Varuna, who are also praised in RV hymns. The tablets suggest that portions of the RV were composed at this time and contribute to a conservative dating by scholars of the formation of the core of the hymn collection between 1500 and 1200 BCE, with the first and last books perhaps added within the next few centuries. This would arguably make the RV the oldest religious scripture still in use in the world. Geographical references in the

hymns, such as to the seven rivers (*sapta-sindhu*), suggest that they derive from the northwest of the Indian subcontinent around the region of the Punjab. Linguistic style is one of the main criteria used for assigning dates to the various literary genres within the Vedic corpus.

The Sama Veda and Yajur Veda Samhitas are liturgical hymn collections that developed some centuries after the RV. The verses in the Sama Veda (SV) are mostly derived from the RV and are presented in melodic forms for an Udgatr, a special class of priest, to chant (*saman*) during Soma offering rites. Similarly, the Yajur Veda (YV) pertains to the rituals of the Adhvaryus, providing these priests prose instructions for the construction of fire-altars, the performance of the elaborate horse sacrifice, and so on as well as the appropriate short verse prayers (*yajus*) drawn from the RV to chant when engaged in these rites. These three Samhitas appear to have formed the core of Vedic orthodoxy for many centuries, until a fourth hymn collection, the Atharva Veda (AV), was included in the fold. Named after the Atharvan, a type of priest, the AV contains over 700 hymns, less complex in metrical style and grammar and different in content from those of the RV. Many of the hymns of the AV are pragmatic, including charms against diseases or to acquire love, spells to inflict harm or counteract sorcery, and prayers to obtain good crops, secure peace, and raise healthy livestock. The magical (both black and white) concerns of this text suggest the presence of religious practices on the subcontinent that differed from Brahminic priestly rituals and that subsequently found expression in alternate spiritual paths such as Tantra. The AV is the first text to mention iron, which only appears in India in about 1200–1000 BCE. Thus, although certain portions of the AV may well belong to earlier centuries, the compilation of the bulk of the text likely derives from this period or later and therefore is contemporaneous with the composition of the SV and YV as well as the Rig Veda Khila, a collection of supplemental verses added to the RV.

The transmission of the Samhitas belonged to various Brahmin theological schools known as *shakhas*, each maintaining the integrity of its version and interpretation. Early Sanskrit texts

mention 5 shakhas (recensions) of the RV, 12 of the SV, more than 40 of the YV, and 9 of the AV. However, only a few of these are extant today, and some only in partial forms. For instance, the YV is found in two branches, designated as the Black YV and the White YV, perhaps because the former is murkier in its structural arrangement than the latter. There are two fairly identical shakhas of the White YV, the Kanva and the Madhyamdina, whose hymn collections are better known as the Vajasaneyi Samhitas. The Black YV is found in three recensions (there is also a fragmentary corrupted fourth version), one of which is the Taittiriya Samhita, whose school has preserved the corpus of its Vedic literature remarkably well.

The Brahmanas, the Aranyakas, and the Upanishads

The Brahmanas constitute the next genre of texts following the Samhitas within the corpus of Vedic literature and arguably derive from about 1200–800 BCE if we do not include the later textual genres sometimes embedded within them. The term “Brahmana” refers to teachings on Brahman, the power believed to inhere in the sacred utterances (*mantra*) of the Vedic hymns and in the rituals that developed in tandem with them. These texts are prose commentaries on Vedic rituals that reflect on diverse priestly concerns, such as why a rite is performed, what constitutes its proper performance, and even the cosmic parallels between priestly actions and the forces of nature. Each of the Vedic *shakhas*

traditionally has a Brahmana associated with it, although only some have survived to the present day. The Aitareya and the Kaushitaki Brahmanas belong to Shakala and Bashkala schools of the Rig-Veda (RV), respectively. The Panchavimsha and Jaiminiya Brahmanas are associated with schools of the Sama Veda (SV), and the Gopatha Brahmana with the Paippalada shakha of the Atharva Veda (AV). Although the Brahmanas of the Taittiriya school of the Yajur Veda (YV) are mixed in with the Samhita portions of the Black YV, contributing to their designation as black, the school does have its own appended Taittiriya Brahmana. One of the most influential members of the genre, due in part to its size and the organization of its contents, is the Shatapatha Brahmana (Brahmana of a Hundred Paths), so-named because it is divided into 100 lessons. It exists in two similar recensions derived from the Madhyamdina and Kanva schools of the White YV.

Chronologically next in the genre of *shruti* literature are the Aranyakas or wilderness (*aranya*) texts, which bridge the focus of the Brahmanas with those of the Upanishads, the last of the four genres. The Aranyakas promoted ascetic renunciation in wilderness retreats. The texts often extend the symbolic interpretation of ritual so that links are made between Vedic deities, natural phenomena, and the human microcosm. For instance, intuitive penetration into the mystery of the vital breath (*prana*) is said to reveal its connection to all sacred utterances (mantra) and to the deities who have created the universe itself. The Aranyakas teach that masterly comprehension of one's interior reality and its fundamental connection to the whole of exterior reality is sufficient to make all of one's ritual acts successful. Thus contemplative realization is valorized in tandem with the priest-craft of the earlier literature.

The relationship between one's authentic self (Atman) and Absolute Reality (Brahman) is extensively developed in the Upanishads. The term *upanishad* ("sit down beside") evokes the image of a student seated at the knee of a spiritual mentor (guru) to receive secret instructions, and the texts are often framed as master-disciple teachings. There are hundreds of Upanishads, but only about a dozen early ones are regarded as

major, granted the status of shruti, and associated with the major Vedic schools. For instance, the Kaushitaki Upanishad is associated with the Bashkala school of the RV, while the Aitareya Upanishad is associated with the RV's Shakala shakha. The Kena and Chāndogya Upanishads belong to the SV, the Taittiriya Upanishad to the Black YV, and the Brihadaranyaka Upanishad to the White YV. As its name suggests, the Brihadaranyaka Upanishad, probably the oldest of the Upanishads, is an Aranyaka classified as an Upanishad. Its linguistic style resembles Brahmana prose, and the text could well derive from as early as the eighth century BCE. These early prose Upanishads evidently predate Buddhism and may be placed in the period from about the seventh to the fifth centuries BCE. The Chandogya Upanishad was once a part of a Brahmana, and the Aitareya Upanishad was contained within the Aitareya Aranyaka, which itself is sometimes classified as part of the Aitareya Brahmana. These six Upanishads form the earliest strata within this genre and are composed in Vedic Sanskrit prose similar to the literature that precedes them. The Kena Upanishad does have two of its four sections in verse that belong to the next strata. Upanishads that belong to this second, later phase, and are composed in verse, include the Isha, Katha, Shvetashvatara, and Mundaka Upanishads. In content they prefigure the theistic devotionism expressed in the Bhagavad-Gita. The Shvetashvatara Upanishad, for instance, associated with the Black YV school is dedicated to the deity Rudra-Shiva.

The Sutras

The final group of texts associated with particular Vedic schools are the Sutras, although these

are not granted status as *śruti*. There are three main categories of these texts: the Śrauta Sūtras, the Grihya Sūtras, and the Dharma Sūtras. Śrauta rites include seasonal public and grand royal rituals such as the horse sacrifice (*ashvamedha*) and kingly consecration (*rajasuya*), while the Grihya texts outline routine domestic ritual procedures, as well as rites of passage. Their linguistic style would place them in the late Vedic period, around the sixth century BCE. The Dharma Sūtras explore duties incumbent on members of the various classes of Hindu society. The earliest of these may derive from the sixth to the fourth centuries BCE. An early representative of the Śrauta Sūtra literature, the Baudhayana Śrauta Sūtra, for instance, along with later compositions such as the Apastambha Śrauta Sūtra, belong to the Taittiriya Samhita of the Black YV. There is also a corresponding Baudhayana Grihya Sūtra, and a Baudhayana Dharma Sūtra also belonging to the Taittiriya school. The Grihya and Dharma Sūtras belong to the first strata of *smṛiti* literature and are thus sometimes called Smṛta (derived from *smṛiti* Sūtras).

The Mundaka Upanishad makes first mention of the Vedāṅgas, or appendixes to Vedic

literature. The Sūtra works mentioned above, together with the Shulva Sūtras, texts on the geometry and construction of altars, are collectively known as the Kalpa Sūtras (Treatises on Ritual) and form one of the six major Vedic limbs or appendages (*āṅga*). The other five are *śikṣā* (phonetics and articulation), *chandas* (metrical structure), *vyākaraṇa* (grammar), *nirukta* (etymology), and *jyotiṣa* (study of luminaries, or, astrology). Panini (ca. seventh to fourth centuries BCE), author of the *Ashtadhyāyī*, a renowned treatise on Sanskrit grammar often dated to the fifth century BCE, provided the foundation for the development of Classical Sanskrit, and marks the end of the period of Vedic Sanskrit literature.

Science and Technology

Some of the most skilled chemists in the period between 4000 BCE and 1000 BCE were the bronze smiths of the Shang dynasty in China (ca. 1600–1046 BCE). Not only were these metallurgists highly proficient technically, understanding the subtleties of the reaction of metals to differing amounts of heat, but they were also creative artists. Producing their art on the outskirts of villages, since the fire and smoke produced in ancient metallurgy would have been too dangerous and unpleasant in the midst of people's homes, these smiths forged elaborate designs that are still striking today in their complexity and, in the words of many art historians, in their ferocity. Most of the bronze vessels were highly stylized forms of ritual vessels that already existed in other media, mostly ceramic and wood. In the Shang dynasty, the technological skill developed enough to allow bronze to be sculpted into equally complex designs. Mostly this was done through the use of composite molds; some vessels that were formed used at least eight individual molds.

The Shang bronzes are representative of the scientific and technological achievements of this era. Combining art, religious tradition, and functionality, these bronzes are evidence of new innovations during this period. Archaeologists reconstruct the science and technology of this period less from written self-conscious treatises on science (although there are a few of these) and more on analysis of the scientific and technical skills required to produce the material culture found in excavations. There seems to have been little interest (with a few major exceptions) in writing down and articulating scientific theory in words. Yet given the technological leaps that are made in this era, this lack of interest in writing about science and technology certainly was not indicative of a lack of practical interest in science.

The basis of the major technological developments between 4000 BCE and 1000 BCE was a more complex understanding of pyrotechnology. Better abilities to control fire and to create greater amounts of heat allowed synthetic materials to play a more prominent role in people's everyday lives. The ability to control fire and heat had existed long before this time, and some of the most important synthetic materials (such as ceramics) had first been produced centuries before. However, greater control of these materials allowed ceramics, metals, and glass to play an equal role with unaltered materials—such as stone, bone, and wood.

The basis of the major technological developments between 4000 BCE and 1000 BCE was a more complex understanding of pyrotechnology. Better abilities to control fire and to create greater amounts of heat allowed synthetic materials to play a more prominent role in people's everyday lives.

The direct result of more sophisticated pyrotechnology was the ability to produce stronger, more complex, and more aesthetically pleasing synthetic objects. Because ceramics, metals, and glass all are similarly dependent on the ability to control high amounts of heat, innovations in the production of one of these materials led to innovations in the others. Kilns, which were typically built of clay and stone, were the most important means of utilizing fire to create synthetics. Pottery or metal in molds usually sat on a small platform in the kiln, under which the fire was built. Building the fire in an enclosed space allows significantly higher temperatures to be reached than building open fires. Fire in an enclosed space allows the amount of oxygen around the ceramics and metal to be reduced, either by limiting how much air enters the kiln or by adding unburned fuel (especially wood) to the flames. It is unclear precisely how hot kilns could get. Since copper was worked and its melting point is 1,981 degrees Fahrenheit, temperatures exceeding this were certainly reached. Iron production does not begin until close to the end of this period; to be worked it has to be kept at a temperature between 1,832 and 2,012 degrees Fahrenheit, which was slightly beyond the abilities of these artisans (or at least was not easy enough for them to make it worthwhile).

The indirect results of these advances were any of the artifacts and buildings that were produced from tools made in a kiln. Metal tools allowed greater sophistication in architecture. Woodworking improved when metal tools were used to sculpt the wood; stonecutting likewise could be done with a greater degree of polish with metal tools. Engineering benefited greatly, as the pyramids at Giza and the palaces of Mesopotamia can attest. Agriculture benefited from less-porous pottery and finer metal tools. Innovations in warfare were deeply rooted in metallurgical advances. Bronze tools gave a significant advantage in combat. Weapons made of wood, such as bows, became more complex, and the advanced woodworking skills allowed the invention of the chariot. Agricultural tools such as the plow came to be widely used in this period, making life much easier for farmers attempting to prepare the ground for planting. Along with these achievements in synthetic production came deforestation. Given the huge amounts of wood required for the kilns (often first converted into charcoal, which smolders longer, or supplemented by animal dung), the first evidence of human-caused deforestation indicates the link between technological achievement and environmental mismanagement.

It should not be assumed, however, that science between 4000 BCE and 1000 BCE was solely geared toward technological development. In those areas where writing was utilized, ancient scholars recorded their observations of the natural world. Although most historians locate the first secular natural sciences in the Greek world of this period, the stirrings of this kind of work began in the preceding era. Mesopotamian scholars were especially concerned with observing nature. These ancient naturalists left behind long lists of animals, plants, and stones, grouped according to taxonomic categories. This type of observation seems to have been driven partly by many of the same motivations that move naturalist today, a profound and genuine interest in the world

around them. These were not the only motivations, however. Many of these ancient observations were made in order to better understand the will of the gods, which were believed to be manifest in the behavior of animals or in the movements of heavenly bodies. By carefully recording observations and attempting to identify patterns, these ancient scholars felt that they could decode messages sent by deities, and much of the science of this period cannot be separated from divinatory practices.

The astronomical skills of the people of this period are attested indirectly in monuments such as Stonehenge (aligned with astronomical phenomena), which reflect a predictive knowledge of astral events. Our most direct evidence for astronomical skills are the writings of ancient sky gazers. Mesopotamian and Egyptian astronomical records are very detailed, and much of our knowledge of Near Eastern chronology is due to the accuracy of these observations.

In order to make astronomical or astrological observations, highly developed mathematical skills were essential. Complex mathematical documents are well attested in Egypt and Mesopotamia, where the equivalent of math textbooks—papyri and tablets that explain how to solve certain mathematical problems—have been recovered. Indirectly, the engineering feats of many of the people of this period reflect knowledge of physics and engineering. Mathematics for the people of this time was mostly a practical skill, although there is number play in the mythological texts of Mesopotamia.

The practical approach to science is also manifest in the approaches to medicine throughout this era. Once again, the best direct evidence for medical science comes from the Egyptians and Mesopotamians, cultures that utilized writing in this period. It is not meaningful to separate religio-magical approaches to healing and scientific approaches in this period, as both were used in tandem. Snakebites (common problems in Egypt and Syria-Palestine) were “cured” through incantations, for example. Diseases in Mesopotamia were often thought to be caused by harmful spirits. Mesopotamian medical practitioners checked their patients for symptoms but not because they thought there was a physiological relationship between the illness and the symptom. Rather, it was believed that symptoms were signs from the gods explaining what the problem was. However, many of the medical practices were efficacious. The Egyptians had an expert knowledge of anatomy, which was utilized in mummification and in surgical practices. Medical examination of mummified bodies has shown that diseases and injuries were often treated successfully.

■ Introduction: Metallurgical Production

Gold, silver, copper, and iron served as the main metals employed in the production of both utilitarian and ornamental objects. The ancient smith could manipulate these metals in their relatively pure state or alter them through alloying or the application of various pyrotechnologies. Copper, typically alloyed in various percentages with tin or arsenic, forms bronze, a harder and more durable metal better suited than pure copper for tools and weapons. Iron technologies followed bronze, but it was not until the tenth century BCE that the percentage of iron tools and weapons increased over the percentage of bronze tools and weapons, and bronze continued to be better suited for some duties.

Smiths require approximately 1,085°C to melt copper and 950°C for bronze, depending on the level of impurities in the alloy. To achieve this heat, smiths could blow air into their furnace either by mouth via blowpipe or through a bellows. The most primitive furnace was essentially a clay-lined hole in the ground known as a bowl furnace. Perhaps the oldest form of bellows was

a simple bag of sewn animal skins or stomach. The bag was attached to an incombustible ceramic pipe (tuyere), which could be inserted into or near the fire and fitted with an opening to introduce fresh air into the bag. The opening was then sealed and the bag compressed to force a stream of air into the furnace. Additional bellows could be added for increased or continuous airflow.

Metalsmiths could either hammer copper/bronze, gold, and silver into a desired shape or cast it in intricate forms. Cold hammering (forging) copper/bronze will increase its brittleness, but this may be counteracted through heat treatment (annealing). Gold is prized for its ability to sustain significant deformation, which allows it to be hammered into paper-thin gold leaf. Casting involves pouring liquid metal into a shaped mold of baked clay, stone, metal, or sand. The lost wax method (*çire perdue*) of casting requires that a representation of the object to be cast be modeled in beeswax (or similar material) and then covered with clay. Specially created risers and vents are added to the wax models of more complex shapes to allow for the escape of gases from the cooling metal. Heating this clay-coated model melts the wax, which runs out through holes provided in the mold. When the mold is sufficiently baked, liquid metal is poured into the spaces left by the wax. The single-use clay mold is broken free from the cast object once the metal has cooled.

In the Bronze and Iron Ages of the Ancient Near East, iron could not yet be cast. Pure iron's melting point is around 1,540°C, a temperature not attainable until the nineteenth century CE. Iron reduced from ore was removed as a lump or bloom (a mixture of solid iron, slag, and pieces of unburned charcoal) that was broken up to remove the iron pieces. Hot iron is ductile (or spongy) and can flatten upon hammering. Wrought iron work can be done by hammering at approximately 700°C. Although wrought iron is softer than alloyed copper, the ductility of iron allows it to survive a blow without breaking, making it a valuable material for tools and weapons. Iron can be welded into larger pieces

Detail of a relief in the tomb of Mereruka at Saqqara depicts metalworkers using blowpipes to force the forge fire, about 2350–2181 BCE. (Werner Forman/Art Resource, NY)

by heating to white heat (1,100°C) in a smith's fire and hammering. An iron tool or weapon could thus be repaired or could be built up and shaped through repeated heating and beating.

Alloying iron with carbon produces steel, which can be stronger than copper alloys. Carburization occurs when an iron object is placed in a charcoal fire, where it may absorb carbon through solid-state diffusion. There is evidence that smiths were intentionally carburizing by at least 1000 BCE, although the quality of the objects was inconsistent. The full potential of steel, however, is only realized when it is heated and cooled under careful conditions. If hot steel is plunged into water or another liquid (known as quenching or fast cooling) a hard, brittle martensite forms. Unless reheated (tempering), the martensite is too brittle for use in weapons and some tools. This reheating could be done at temperatures well below red heat (750–900°C). Quenching has no effect upon bronze or upon iron that is not alloyed with carbon.

The equipment of metalsmithing appears fairly standardized. A hammer and a working surface/anvil were essential for forging, and a ceramic or stone crucible was required to hold molten metal for casting procedures. The crucible served equally well for smelting, melting (or remelting scrap), and refining operations. The removal of excess metal from a cast and the breaking up of scrap would require a heavy-duty chisel, commonly known as a cold chisel. Stone tools, rounded without handles, appeared in the metalsmith's tool kit for use in hammering, pounding, grinding, or crushing. Stones were also used as whetstones for sharpening edges and as polishing abrasives. Specialty tools, such as swages (used to create a rod or tube) or forceps (to move and hold hot objects) might also appear in the smith's tool kit along with tools for detailing or decorating the finished pieces.

Part- and full-time craftsmen lived and worked among the population, with many smithies integrated into residential areas rather than separated in purely industrial quarters. Some metalsmiths traveled between settlements carrying their tools, raw materials, and techniques with them, although this was likely not commonplace.

—Adam Aja

THE ULUBURUN SHIPWRECK

A late-fourteenth-century BCE shipwreck discovered near Uluburun, Turkey, revealed a shipping cargo that included tons of Cypriot copper and other raw materials. The copper was shipped in several forms that included two-handled, pillow, planoconvex discoid (bun), and four-handled ingots. The four-handled ingots, also known as oxhide ingots because of their similarity to dried ox hides, each weighed approximately 52.9 pounds (24 kilograms). Ingots of nearly pure tin were also part of the cargo. The raw material from the ship would have been enough to manufacture well over ten tons of bronze. In addition to the metallurgical material, the cargo included glass ingots, food-stuffs (olives, figs, pomegranates, spices, and nuts), terebinth resin, ivory, and manufactured goods such as jewelry, Cypriot pottery, tools, and weapons. While the origin of the ship, its crew, and most of the cargo is uncertain, it is apparent that the ship was at home along the Syria-Palestine coast.

Egyptian Goldsmithing

The eastern deserts of Ancient Egypt were rich with gold. There were three main regional concentrations: at Qena and Qift, at Elkab and Edfu, and at the mouth of the Wadi el-Allaqi in ancient Nubia. Gold existed in the alluvium of the wadi beds, from which it could easily be panned by unskilled labor, and in veins of white quartz to be mined from the igneous rock of the hills

➤ GOLDEN BODY-PART REPLACEMENTS

Amulets in the form of human body parts were discovered among the golden ornaments adorning mummies. These were not, however, intended as purely decorative pieces. The Egyptians believed that the miniature parts would function as substitutes in the afterlife should the original part of the body become damaged or destroyed. The use of these body-part replacements increased after the First Intermediate period. In the New Kingdom, the practice of covering the mummy's fingers and toes with gold replicas was introduced. Fingers and toes were especially delicate parts of the mummified corpse. The gold replacement digits even included gold fingernails and rings.

—Adam Aja

between the Nile River and the Red Sea. Gold preparation was often done near the mines, and craftsmen would typically receive their gold bagged as dust or nuggets or molded into ingots. Scenes painted on the walls of the Tomb of Rekhmire (late fifteenth century BCE) depict goldsmiths receiving a weighed allotment of ring-shaped gold ingots. Most Egyptian gold was impure, containing up to 20 percent silver (technically termed “electrum”). A considerable amount of Egyptian goldwork was melted down in antiquity, and with only a few exceptions (notably from the tomb of Tutankhamun), most surviving pieces of goldwork are small. These limited glimpses, however, inform us of the high level of skill attained by Egyptian goldsmiths.

Craft production was often associated with the palace or temple, institutions that could afford the investment in long training and slow labor-intensive work. The best craftsmen were trained from boyhood and might attain high social status as adults. It was unlikely that many nonelites owned or worked gold, a metal that was prized for its role in international diplomacy and religious symbolism. Gold was considered the flesh of the gods. Its color was like that of the sun and did not tarnish, so it served as a symbol of the purity and everlasting nature of the gods.

Goldsmiths could produce finely crafted objects from either cold-worked or molten gold. Gold is extremely ductile and can flatten into

paper-thin sheets of gold leaf through repeated hammering with simple rounded stones. Gold sheet was used to decorate wood furniture, statues, architecture, and funerary items. Thick sheets of gold could be hammered directly onto wood and held in place by small gold rivets, while thin sheets were attached by adhesive. The rough surfaces seen on some recovered artifacts indicate that they were robbed of their original gold covering. Thick sheets of gold could also be shaped on an anvil to raise intricate forms, including masks and vessels. Predynastic gold ornaments were simple beads of sheet metal or foil over a core, but soon after gold was being cast like bronze into intricate forms. Gold could be used by itself or combined with semiprecious stones such as lapis lazuli, turquoise, or carnelian. Gold jewelry was worn on most parts of the anatomy by both men and women. The basic types of jewelry were generally established by the end of the Old Kingdom, although earrings appeared later at the end of the Second Intermediate period. Not all jewelry was purely decorative. Jewelry could indicate rank, represent a military or civil award, and provide protective power. Ornamental flies made of gold, ivory, or semiprecious stones were awarded for acts of military bravery.

Decoration could be applied by several techniques. Relief designs could be pressed into the surface of the object with a hand punch from the back (repoussé) or from the front (chasing). Although repoussé and chasing tools varied in size and shape, the edge was generally rounded since the tool was required to groove, not cut the metal as it was stamped or punched onto the surface by a series of hammer blows. There were no cutting shears in ancient Egypt. Panels could be cut out by punching through the gold sheet with a sharp chisel. Wire was made by chiseling off strips from the edge of the gold sheet or by cutting a spiral pattern for longer threads.

Syro-Palestinian Weapons

Opponents in war often sought to gain superiority over enemies in mobility, security, and fire-power. Superior mobility could come through chariots or cavalry, while armor and constructed defenses provided security. Weapons provided the long-, intermediate-, and short-range fire-power needed to strike at a foe. Combatants used shock weapons for striking and thrusting in hand-to-hand skirmishes and missile weapons for shooting and throwing. Most armies in Syria-Palestine were organized into units linked with specific types of weapons since it was impossible for soldiers to carry all weapons for all ranges. Given that most weapons were composed, at least in part, of degradable material such as wood or leather, our knowledge of Syro-Palestinian weapons must come from several sources, including textual references, iconography, and archaeological remains.

Handheld shock weapons included the club, mace, ax, knife or dagger, sword, and spear or lance. A simple club, which consisted of a heavy length of wood, was similar to the form of the mace. Both the mace and ax consisted of a short wooden handle set with a stone or metal head. Ax heads were light and sharp, while mace heads were blunt and heavy. The bladed ax heads of the Early Bronze Age changed toward a more pointed profile in the Middle Bronze Age. This evolution may have been necessary to penetrate bronze body armor, which had not previously existed. In comparison to the mace and ax, sword and dagger production required a large amount of metal. Consequently, it is not until the development of iron technology following the Late Bronze Age that we see a rise in the use of blades. Swords could be long and heavy, requiring great skill to wield, although few examples survive. Most swords would be considered long daggers for stabbing with a straight blade tapering to the tip. The striking sword had only one sharp edge, with the thickest part along the blunt side. The sharp edge could present either a convex or concave curve. The term “knife” is

Man with a sling-shot, from Tell-Halaf, Syria, mid-tenth century BCE. (Erich Lessing/Art Resource, NY)

generally reserved for single-edged blades used for domestic, agricultural, and industrial purposes. These blades could vary a great deal in size and had a variety of specialized forms and functions. Blades with lengths of less than four inches (ten centimeters) were likely never intended for warfare. It seems possible that large domestic knives served as fighting blades in times of need. The spear was heavier and bigger than the javelin and was used to thrust like a very long stabbing sword. It had a stout wooden shaft and a metal head and was sometimes capped with a metal base. The socketed spear-head of the Middle Bronze Age largely replaced the tanged head (the base of which was inserted into the shaft) used in earlier periods.

Intermediate and long-range weapons (slings, bows, and javelins) were normally used at the outset of battle to thin out and weaken an enemy for the charge of the shock troops using hand-held weapons and served equally well in hunting. The sling was made from a small strap of leather or cloth with attached cords. A slinger

➤ NAHAL MISHMAR

A hoard of Chalcolithic (ca. 4300–3300 BCE) metal objects was discovered near the Dead Sea in Nahal Mishmar, at the so-called Cave of the Treasure. The hoard of more than 400 artifacts included chisels, axes, decorated standards, and crowns and over 200 mace heads wrapped in a fiber mat. The objects may have served as ceremonial or prestige items rather than as utilitarian tools or weapons. The artifacts were made by the *çire perdue* technique of a copper-arsenic-antimony ternary alloy, a blend apparently reserved for ceremonial objects and only appearing during the Chalcolithic period. The source of the metal ore is uncertain, although it may be sought in eastern Anatolia.

—Adam Aja

placed a stone in the strap and swung the apparatus overhead until it gained sufficient momentum. Releasing one of the cords fired the stone missile. One rare example of a preserved bow made from olivewood was recovered in the Chalcolithic Cave of the Warrior. This self-bow, constructed of a single piece of wood, was quite accurate over short distances but was a bit unwieldy in terms of length. Later technology allowed for shorter bows to be constructed of laminated wood, sinew, and horn; these bows had a range of more than 820 feet (250 meters). These composite bows may have originated in Mesopotamia during the mid-third millennium BCE. The body of the arrow to be fired had to be long, straight, and light. Reed made the best arrows, but wood was quite common. The tail, made of feather, was designed to keep the arrow on its course in smooth and straight flight. The point could be stone, metal, bone, or hardened wood. The javelin (or light spear) was constructed similarly to the arrow. It was composed of a straight wooden shaft affixed with a hard point for piercing flesh. The javelin was hurled by hand, and soldiers could have several. To increase the javelin's range, a cord could be attached. This was wound around the shaft and held so that as the javelin was hurled, the unwinding of the

cord would give a spin and thus a steadier flight to the projectile. The base of the shaft might be fitted with a metal point to allow the javelin to be stuck in the ground during a rest period. This base would contribute speed and balance to its flight. Points that are considerably longer and heavier are generally spearheads.

European Metallurgy

While metal production developed as early as the sixth millennium in some parts of Europe (such as the Balkans), the use of metal becomes significantly more widespread around 3000 BCE and is associated with the Late Neolithic period. Advances in archaeological knowledge have made it clear that copper actually came into use before what is referred to as the Copper Age (Chalcolithic period) and that bronze came into use before what is referred to as the Bronze Age.

The two most important components of metallurgy are the ores from which the metals are derived and the fuel that is used to heat the metal. Throughout the Copper and Bronze Ages in Europe, there is clear evidence of wide deforestation that may be related to the chopping down of trees to produce charcoal for fuel. It is less clear where ancient Europeans procured their ores. It is likely that much of the metal re-

Bronze lurs (wind instruments) from Bronze Age Denmark. (Erich Lessing/Art Resource, NY)

sources came from above-ground deposits that have long since been completely mined away. There are, however, isolated mine sites that may have been in use as early as the Bronze Age. Metal ores were likely traded widely throughout Europe. Metal was transported in unfinished form in what are called *ossenringe*, metal coils of varying sizes.

Metallurgy in northern Europe during the Bronze Age is quite noteworthy. Since metal is not found in this region, it must have been imported from the south. Archaeologists have not recovered much metal from settlement sites; most has come from hoards found in the northern marshes. The types of metal tools are quite diverse. What is peculiar is that many look quite nice but would not have been very functional. Wide-bladed axes make up a significant component of the corpus; these look quite fierce but are too weak to have been useful in a battle (or against a tree). Lurs are long horns with a smooth surface and rough interior, meaning that not much care was taken in the type of

THE THREE AGE SYSTEM

Metal technology has been one of the most important diagnostic features for European archaeology for the period from 4000 to 1000 BCE. In 1836, the Danish scholar C. J. Thomsen published a system of chronological nomenclature (Stone Age, Bronze Age, Iron Age) for Europe based on the appearance of various types of tools. This system is still in use today although in significantly modified form. Most notable is the addition of the Copper Age (or Chalcolithic Age) to the system.

—Kevin M. McGeough

THE LOST WAX METHOD

In the period between 1000 BCE and 300 CE, metalsmiths had a simple but ingenious method of producing elaborate metal objects. Called the lost wax method (a translation of the French name *çire perdue* more typically used by scholars), this technique was used all over Europe, Asia, and Africa during this period (and is still used worldwide today). The artist starts by carving the desired object out of a piece of wax. For instance, if the artist wanted a sword, he would carve a wax sword. Once finished, the artist would cover the wax with wet clay and put the whole object into a kiln. As the clay hardened in the heat of the oven, the wax would melt away, leaving a ceramic mold of the object. Once the mold cooled down, the smith would add molten metal to the mold and then wait for the metal to harden and cool. Once this was complete, the artist would break off the ceramic mold and reveal an elaborate metal object, a very close replica of the original (although now lost) wax sculpture.

—Kevin M. McGeough

sound that they would produce. Dots, circles, arcs, and ribbons were typical decorations on this metalwork.

It is the Carpathian Basin, in what is now Transylvania, where the most innovative European metallurgy occurred during the Bronze Age. In this region, smiths added arsenic to copper to

make it harder and improve the ability to cast it. The most typical metal item produced in this region is the battle-ax, made with a two-piece mold. Usually it is only the ax head that is found but because of the shaft hole built into the ax head, we can be certain that a handle (probably wood) would have been inserted into the tool. In terms of design, the c-scroll is typical of this region, although it became popular throughout the rest of Europe as the Bronze Age progressed.

■ Introduction: Subsistence Technologies

From 4000 to 1000 BCE, changes in subsistence technology are apparent throughout the world. Where agriculture developed or continued to develop, the invention of tools such as the plow increased agricultural production. Innovations in production technology (such as manos and metates) improved the ability of people to transform crops into food that was tastier and in some cases more nutritious. In those locations where metallurgy developed, the use of metals in the manufacture of food-production tools likewise contributed to the ease and diversity of food production. Stone tools also continued to be utilized and improved upon, especially by those societies that were reliant on hunting and gathering forms of subsistence. In Australia, for example, changes in stone tool manufacture in this period are apparent, especially the utilization of more diverse types of stone. In North America, smaller projectile points come to be used during this time, setting the stage for the later development of the bow and arrow.

Pottery was one of the most important subsistence technologies found throughout much of the world from 4000 to 1000 BCE. Due to how well ceramics survive archaeologically, they are important artifacts in the archaeological analysis of cultural change and the dating of sites. Their importance to the subsistence practices of ancient people should not be underestimated. Their appearance in North America has been charac-

terized as a "container revolution," and although they appear much earlier in the Near East, Europe, and Asia, ceramic production technology improves dramatically over this period.

—Kevin M. McGeough

The Plow

Plows are one of the oldest agricultural tools still in use today and were fundamental in the spread of cereal agriculture throughout the world. The term "plow" covers a wide variety of types of tools, but all are used to prepare soil for planting crops. Farmers use plows to dig up the top layer of soil, making the ground more suitable for sowing; to bring fresh nutrients to the surface; and to bury other plant remains to facilitate decomposition. Although presumably invented around 6000 BCE, the earliest archaeological evidence for the use of the plow dates to about 3500 BCE. Advances in metallurgical technology later led to significant advances in plowing technology.

The earliest plows were used like hoes, with humans dragging the plow behind them through the field. Called scratch plows today, using these tools would have been back-breaking labor. Where available, the human labor was replaced by animals or teams of animals. In ancient times oxen were yoked together (in Europe and the Near East), and the plow was attached to the

yoke. The oxen would be led across the field, dragging the plow behind them through the soil.

Bronze Age plows have survived in the European archaeological record. These plows take one of two forms, but both forms are primarily made from wood. Two-piece plows have a long main pole that is attached to a smaller ard that points backward 30 degrees. The end of the ard is shaped like a point. One-piece plows were shaped the same but were formed out of one piece of wood and generally worked better than the two-piece plows. However, one-piece plows would have broken more readily. In the Near East, metal ards have been recovered from sites in Israel. These ards are shaped like pipes (so that the pipe end can fit over the top of a wooden pole). The other end of the metal ard is pointed just like the wooden types.

There is much other archaeological evidence for the use of plows from 4000–1000 BCE. Plow marks in the dirt are often preserved at sites. Plows yoked to oxen are depicted in Egyptian tomb paintings and are the subject of models left in the tombs, since the Egyptians believed that these models could be used as real plows and plow teams in the afterlife. Plows are also frequently depicted in art. Plows appear on very early Mesopotamian cylinder seals, in Mesopotamian wall reliefs and stelae, and in European rock art.

Sub-Saharan African Technologies

The development of technology in Africa south of the Sahara between 4000 BCE and 1000 BCE was necessitated by the needs of Neolithic societies transitioning from food gathering to a sedentary life. Thus, archaeological finds reveal that many settlements south of the Sahara in this pe-

Detail of a fresco in the tomb of Sennedjem showing the tomb owner plowing and his wife seeding flax or wheat, Nineteenth Dynasty, about 1295–1186 BCE. (Bojan Breceelj/Corbis)

ANCIENT PLOW MARKS

Archaeologists occasionally find plow marks at sites, presumably left by ancient farmers who, for whatever reason, did not return to farm that particular patch of land. In Europe, many of these plow marks are found under large burial mounds, called barrows. Under barrows, these plow marks often intersect one another at right angles, indicating that plows were not used in these to prepare the land for farming. Rather, it seems that plows were used to prepare and level the ground for construction projects. Thus, the plow is not just an ancient farming tool but is an ancient building tool as well.

—Kevin M. McGeough

riod were already engaged in technological production such as microlithic industry (small stone tools), bone industry, and ground stone axes. Some settlements even produced pottery alongside the lithic industry. The microlithic technology was used for hunting and food gathering in most locations, but at the coastal and lacustrine areas it was also used for fishing and the gathering of shells.

Prior to archaeological finds in the equatorial forest of Africa, it was often stated that human beings may not have lived in that zone before

➤ TYPES OF TOOLS FOUND AT IWO ELERU

Archaeological excavations at Iwo Eleru revealed a production industry for small flakes of quartz and chalcedony. There were tools with varied shapes, which implies that they were used as convenient for different tasks. Among them are:

- Struck stone: Used as a hammer.
- Chopper: Piece with bifacially flaked chopping edge.
- Pick: A trihedral piece flaked on three faces that converge to a point.
- Heavy-duty scraper: A pebble or tabular piece with very steep scraper retouch.
- Chipped axe: Adzelike pieces showing no ground surface.

—*Tolulope Lawrence Akinbogun*

the advent of the Iron Age due to the thick vegetation that had made the environment difficult for human beings to exploit. However, Thurstan Shaw's discovery of a rock shelter in this ecological zone at Iwo Eleru in western Nigeria revealed the activities of people in the environment during the Stone Age.

Late Stone Age materials excavated at the rock shelter of Iwo-Eleru in western Nigeria included stone axes. Also, at another rock shelter in Rop on the Jos Plateau in northern Nigeria, ground stone axes as well as pottery that were associated with microliths were found. At Mejiro Cave in Old Oyo Nigeria, microliths were found; this site is distinctive in having a high proportion of tool kits and a high number of flakes per core. At Dutse Kongba, also in Nigeria, excavators divided the lithic industry into three phases: aceramic microlithic industry (fifth to fourth millennium BCE), concentration of microliths with some pottery (fourth to third millennium BCE), and mixed deposit of microlith and some pottery, two pieces of ground stone axes and some iron (ninth century BCE and seventeenth CE).

Other Late Stone Age traditions in Nigeria (Daima, Kursakata, and Shilma in Borno, 1000 BCE) have no microliths at all but do have a bone industry, ground stone axes, and pottery. The Bama Road site in Borno Nigeria extends back

to the second millennium BCE. Its inhabitants produced ground stone axes, bone points, a few quartz flakes, and pottery. However, along the same zone in Rim Burkina Faso, microlithic industry with plentiful segments and backed pieces were produced, without pottery and ground stone axes. The Rim site is dated before 3000 BCE.

The geographical areas of present-day Ghana also yielded archaeological finds that revealed much about the subsistence technology of the Late Stone Age. The Achimota Cricket Pitch site produced an aceramic microlithic industry. Among the stone artifacts found in this site are blades, points, crescents, scrapers, burins, and fabricators. The Bosumpra Cave, in Abetifi in Ghana, yielded an association of pottery, ground stone axes, and microliths; the items were dated 3400 BCE–1200 CE.

To the west of Nigeria in the northern fringes of Ghana, a rock shelter excavation yielded ground stone axes, pottery, and microliths. Excavation at Nsuta produced assemblage of Late Stone Age materials (an association of microliths, ground stone axes, and pottery). And the Kumasi University sites in Ghana produced an assemblage of Late Stone Age materials of Kintampo culture. The Kintampo culture is characterized by thick soft pottery that is much decorated, small ground stone, axes, and microliths (fluted stone cylinders, grooved bead polishers, arrow polisher, stone arm rings, and burnt daub). It is also characterized by terra-cotta cigars, pieces of abrasive material of elongated almond shape. The name "terra-cotta cigar" derived from its cigar-shaped profile. A typical artifact assemblage found at Late Stone Age East African sites includes microliths, stone bowls, pestle rubbers, polished stone axes, ostrich egg shell, and beads. The ceramics are generally round-bottomed pots, decorated incisions, and stamps.

Flaked stone was used by the Nubians for cutting up meat and for cicatrizing themselves. Pieces of flint were used by the mountain people of New Guinea in the carving and sharpening of arrows. Scholars have argued that in the Late Stone Age of southern Africa, there was a relationship between the occurrence of small convex scrapers and leather working, and such artifacts in profusion may indicate that their mak-

ers were wearers of leather clothing. Such finds made likely the probability of leather working among the Iwo Eleru in Nigeria due to the increasing occurrence of complete scrappers over time in the area.

However, at the Ntereso site in Ghana, an Iron Age technology was found to have existed contemporary with Late Stone Age technology. This and other finds make the site unique in the Late Stone Age of West Africa. The site revealed a subsistence technology that was a mixture of elements recognizable as normal to the terminal Late Stone Age of the area and other elements regarded as intrusive.

Aside from the lithic and bone industries, pottery was the other vocation of the Late Stone Age south of the Sahara. Pottery from Rop in Nigeria were bowls with inward-directed rims and pots with averted rims above a neck. The pottery of the Neolithic in Africa south of the Sahara was decorated on the surface by roulette and incision. In Rop pottery, roulette was achieved with the use of plaited fiber. At Afikpo, the Ukpa rock shelter revealed the production of thick coarse red ware with heavy temper decoration made by channel grooving and comb stamping. The Late Stone Age pottery from Ntereso is one of the largest collections of excavated Neolithic pottery in West Africa. The commonest are cooking pots with everted rims (turned out and up) and globular or open bowls. The pots were decorated by grooving and comb impression. Some of them were burnished. Kintampo pottery on the other hand is characterized by the use of comb stamping, often with oblique impression on the shoulder. Most of the pottery from the Bama Road site in Borno, Nigeria, is described as being plain, although some were decorated with toothed stamp or incisions.

Projectile Point Technology in North America

Over the span of the Holocene era projectile point technology changed greatly in North America, beginning with the large bifacially flaked points of the earliest Americans (e.g., Clovis and Folsom points) to small side-notched points used with bows and arrows. Overall projectile points were reduced in size as flaking techniques became more sophisticated, and the means by which these points were projected became more efficient. Although large flaked points continued to be used until about 5000 BCE across much of North America, evidence indicates that smaller projectile points did not become common until around 3000 BCE. Subsequently, when the bow and arrow was adopted around 450 BCE, projectile point technology reached its climax. During this progression in projectile point technology, prehistoric North Americans also changed the means by which they projected these points. Beginning with the atlatl and its use of spears and darts, the technology slowly shifted until the bow and arrow was almost universally adopted.

Throughout the Early and Middle Holocene, prehistoric North Americans used the atlatl, which was a stick or board used for throwing spears or darts, as their primary form of projectile technology. The earliest evidence for atlatl use in North America comes from Lake Winnemucca, Nevada, and dates to the Early Holocene period. Atlatls consisted of two parts: a handle and a mechanism for articulation with the spear or dart. The handle was either carved or possessed one or two loops through which the hand or two fingers were inserted. Opposite this end the handle contained either a male or female member. The male type contained a projecting part, usually a spur or a hook, that was inserted into a concavity of the spear or dart. The female type consisted of a depression in the board into which the end of spear or dart was inserted. Evidence indicates that spears or darts thrown from the atlatl were able to travel greater distances with more force than if just thrown by

► PROJECTILE POINT TECHNOLOGY IN THE GREAT BASIN

Like other regions of North America, projectile points became progressively smaller in the Great Basin as technology allowed the scaling down of large bifacially flaked spear points to small side-notched points used to tip arrows. The Great Basin provides a particularly clear record of this technological progression beginning with early Clovis, Folsom, Scottsbluff, and other large stemmed and unstemmed points. By 6000 BCE, side-notched points appeared as hafting technology developed, and by 4000 BCE projectile point sizes decreased in overall size, as exhibited in Elko and Pinto series points. Beginning around 2,000 years ago, projectile points reached their apex in design with the introduction of the bow and arrow. The other unique characteristic of Great Basin projectile point technology was the fact that the bow and arrow, despite its superior technology, was not adopted in the region until relatively late in prehistory, while other regions adopted the technology much earlier.

—Peter N. Jones

hand, a fact that would have given prehistoric North Americans greater range in their hunting pursuits. Dart and spear points were usually large bifacially flaked stone points suitable for hafting on the end of a shaft. Like arrow shafts, very few dart or spear shafts have been recovered, making it difficult to determine exactly how lithic points tipped the shaft of the dart or spear.

The archaeological evidence from the Lower Columbia River valley is characteristic of the shift from dart and spear technology to bow and arrow technology. Beginning in the Early Holocene, prehistoric peoples used large bifacially flaked points that were projected either by hand or by use of the atlatl. Data indicates that by 2,500–2,100 years ago subsequent broad-necked, corner-notched points used with spears or darts gave way to small narrow-necked points and that by 1000 CE small side-notched arrow points had become common.

A similar progression is found in projectile point technology for the Great Basin. Beginning

with large bifacial knives and stemmed and concave-base projectile points with edge grinding, the technology gave way to smaller points that tipped atlatl darts by 5000–3200 BCE. The atlatl, which may have been present in the Great Basin as early as 7000–6500 BCE, continued until at least 2,900 years before the present, while atlatl spurs or hooks from the southern San Joaquin Valley in California date to 6360–5650 BCE. Atlatls in the Great Basin were often carved from a very hard wood, usually mountain mahogany (*cercocarpus ledifolius*). It is not possible to determine precisely when the atlatl was replaced in the Great Basin by the bow and arrow, although evidence from Hogup and Danger caves in western Utah suggest that it was around 1000 BCE–1 CE.

The question of when bow and arrow projectile point technology emerged in other parts of North America is still unknown, and the organic parts of the technology have only been preserved in some regions such as the Great Basin, the Southwest, and the Ozark Mountains. Evidence indicates that the bow and arrow first appeared in the Columbia River area around 500–100 BCE, replacing the use of the atlatl in the region. In the Northeast, the bow and arrow arrived much later. For example, evidence from Klunk Mound 8 indicates that the bow and arrow did not arrive in the area until circa 600 CE. Prior to this, projectile point technology consisted largely of various stemmed or notched points such as the Palmer, Kirk, Cypress Creek, and various other bifurcated-base forms that were used to tip spears or darts of various sizes.

Not all regions appear to have developed the bow and arrow. For example, on the northwestern coast evidence indicates that prehistoric peoples never used the bow and arrow and that projectile points remained either fluted or stemmed in design throughout the Holocene era. These projectile points are thought to have been used in hunting various mammals of the region, primarily by means of spears.

The Australian Small Tool Tradition

The so-called Small Tool Tradition appears in temperate Australia around 2000 BCE. The name refers to the distinct types of microliths that first date to this period in Australian prehistory. Most typical are what archaeologists call backed points, so-named because one edge is designed to be dull so that the tool can be held in the hand (without cutting the hand) or can be placed into a haft or handle. Bondi Points are one type of these backed Australian Small Tools, which were used until about 500 CE (about 2,500 years). It should be noted that some scholars, such as Kamminga, argue that this should not be considered a unified tradition, since many of the tools look very different. Most Australian archaeologists, however, still see some unity in

THE DINGO

Around the same time as the Australian Small Tool Tradition, the dingo made its first appearance in Australia. Scholars are divided as to whether or not these two phenomena are related. The Small Tool Tradition seems to have developed out of local styles; dingoes came from elsewhere, suggesting that the correlation is coincidental. While clearly having been imported from outside Australia (probably from Southeast Asia), once the dingo arrives it quickly spreads throughout the continent. It is not entirely clear who would have brought the first dingoes; the best candidates are Austronesian traders who exchanged goods with the Australian Aboriginal population. It is also not clear if dingoes spread across the continent on their own (in packs) or as companions of Aborigines, although a combination of these two factors is most probable. Modern ethnographic analogy shows that Australian Aboriginals would use dingoes to help with hunting and that dingoes sometimes lived alongside the human population. Very likely this was the case in the period between 1000 BCE and 300 CE as well.

—Kevin M. McGeough

the design of these tools, especially in the backed microliths.

Scholars initially thought that these microliths were introduced to Australia from Southeast Asia. So far it has not been possible to identify Southeast Asian precursors to these tools. Thus, scholars have reevaluated this thesis, and now most believe that this is an Australian innovation. Although the Small Tool Tradition is attested throughout temperate Australia, there is significant local variation in the types and styles of tools. This probably reflects regional adaptation based on specific environmental differences and cultural preferences. The significant regional variability further suggests that these microliths were not tools introduced from elsewhere but instead were tools first knapped in Australia. The dates available for the earliest microliths are contested by archaeologists; however, the earliest examples of the Small Tool Tradition seem to come from southeastern Australia, which is not what one would expect if these had been brought to Australia by Southeast Asian traders.

The Small Tool Tradition coincides with a drastic increase in Australian sites. Scholars initially thought that this reflected a growth in population density and subsequently greater intensity of food-acquisition practices (mostly hunting and gathering). Recently, the scholarly consensus has shifted somewhat and regards this increase in amounts of sites as reflecting better archaeological preservation. The small tools do reflect a growing use of more exotic stone materials (stone materials that are rarer, found in only certain locations). So while these microliths may not reflect a growth in population, they most certainly reflect a complex exchange and transportation network.

Regional Ceramic Traditions

During the period 4000 to 1000 BCE, ceramics take the same general form, and thus archaeologists have relatively standardized means of describing different types of vessels. Generally, vessels are described as either open or closed. The difference between open and closed is somewhat loose, but usually if the mouth of the vessel is the widest part, the vessel would be considered open. Plates and bowls are typically considered open vessels. If the mouth is narrow, then the vessel is closed. Jars and bottles are usually considered closed since they are intended for storage and/or transportation. Beyond this basic division, the forms and styles of vessels vary around the world. In most regions there seem to be many types of ceramic vessels that were designed to resemble vessels made of other mate-

rials, such as woven baskets or fishnets. What follows is a brief introduction to some of the most noteworthy ceramics of this period.

Egyptian ceramics were made of two types of materials—Nile silt or marl clay—and these materials determine the color and texture of the particular vessel. Some early Egyptian ceramics were painted with elaborate scenes. Others have red-colored bottoms and uneven black tops, created by embedding the vessel top-down into the kiln. The carbon from the smoke colored the top of the vessel black but left the bottom a rich reddish color. The most common pottery finds at any Egyptian site are bread and beer vessels. Bread vessels were molds in which bread was baked. These molds changed in shape throughout Egyptian history but were usually quite roughly made, and the walls were very thick. Beer vessels also changed shape, but most were also quite rough and porous. The porous beer vessels sweated, actually helping to cool the beer and make the rough ceramics more pleasant to drink from.

In Greece, from the earliest Greek times, pottery making was an art. Greek pottery was traded around the Mediterranean; its beauty and fine quality (along with the contents of these vessels) made Greek pottery a luxury item and an object of social status. Mycenaean ceramics are particularly noteworthy for their fine manufacturing quality (made on a wheel and highly fired) and their elaborate painted decorations (ranging from abstract geometric designs to birds to chariot scenes). Kraters were a very common form of Mycenaean pottery; these were large bowls used for mixing wine. Cypriot pottery is also noteworthy. Small vessels called bilbils were traded around the Mediterranean. Bilbils are shaped somewhat like poppy seeds, leading some scholars to suggest that these may have been ancient opium containers, although there is minimal positive evidence to support these conclusions.

In the Near East, Syria-Palestine has a long history of elaborate ceramic manufacturing, exporting their ceramics to Egypt and Mesopotamia. The repertoire is truly vast, so only a few types can be mentioned here. Fundamental to ceramics of this period were the large store jars called pithoi (or in the singular, pithos). These

were large oval-shaped vessels. The bases were rounded, which may seem unusual for a store jar. However, floors were usually dirt in Syria-Palestine, making flat-based vessels difficult to balance. Rounded bases could be jammed into the dirt and stabilized. Pilgrim flasks, a much smaller type of vessel, look like modern canteens; archaeologists often find these within the building walls, likely left as foundation deposits or offerings to the gods during the construction of the building.

In the Indus Valley region, pottery forms—unlike many classes of Harappan material culture—varied significantly from city to city, which speaks to a diversity of local ceramic traditions. Both wheel- and hand-made pottery were manufactured, and some larger vessels were made out of separate components, put together just prior to firing. The actual forms of the pots show a familiar range of styles; the large pedestaled store jars, though, are distinctive of the Indus Valley. Also unique are perforated cylindrical jars, which were probably used as strainers given that the entire vessel was perforated with tiny holes. Cooking vessels were likewise distinct, with very rounded bottoms that allowed even heat distribution and prevented the vessel from tipping. The rounded bottom often appears exaggerated by the tall, straight neck and outward-flaring rim. Most Indus Valley pottery was covered with a red slip; black paint was used to add designs on top. Other color paints, while not unknown in the Indus Valley prior to the rise of the Harappans, were not very common, or at least polychrome paint has not survived well archaeologically.

In China, ceramics show marked regional differentiation, which is consistent with the current consensus that the Neolithic period in China hosted numerous small and independent cultures. Among many of these cultures and extending well past the Neolithic in its usage was the traditional Chinese water jar. Water jars were oblong in shape, with small handles located at the midpoint of the vessel. Ropes were drawn through these handles, and the vessel would be extended into a river, mouth down. The vessel would fill up with water and then would be pulled out of the water. As the vessel was pulled out, its center of gravity would cause it to flip

➤ IMPORTANT CERAMIC TERMINOLOGY

(Joseph K. Crea)

Ceramicists use specialized terminology to describe the various components of a ceramic vessel. The main part of the vessel is the body. The very bottom is the base, which is often further specified by shape. So, for example, a ring base is a base that is shaped like a ring. The top of the vessel is the rim, and the opening is usually referred to as the mouth. Handles are obvious, but the neck may not be. The neck is the part of some vessels where it narrows toward the rim. An everted neck, however, flares outward. A sherd (not a shard) is a broken piece of pottery. Often archaeologists are familiar enough with ceramic traditions that they can reconstruct an entire vessel based on a single diagnostic sherd. Typically a diagnostic piece is a base, rim, handle, or painted fragment. Decorations are also referred to with this type of standard language. Appliqué is any smaller pieces of pottery added on to the main vessel; handles are the most common type of appliqué. Incised decorations are carved directly into the vessel. Slip is similar to paint but is essentially a ceramic-based dip that the vessel is covered in prior to firing in the kiln. Wash is a very light slip. Monochrome pottery has one color, bichrome pottery has two colors, and polychrome pottery has more than two colors. Burnished pottery is very shiny; the shine is the result of a harder object being rubbed vigorously against the vessel.

—Kevin M. McGeough

over, and the mouth of the vessel would then face upward so as not to spill any of the water.

Chinese potters also produced ceramics with very elaborate design schemes. Vessels with tripod and ring bases become increasingly common throughout China during the Neolithic period. This may be a functional development because tripod bases conduct heat well, so these were likely cooking vessels. Tripods with hollow legs made especially good steamers. Eggshell pottery is very thin, feeling fragile to the touch. Frequently, different sections of the vessels would be constructed separately and then fitted together just before firing. Eggshell pottery is often black in color, not from paint (although vessels painted in other color schemes are well attested) but from the addition of wet firewood to the kiln, causing smoke (and thus carbon) to envelop the pottery. Many other types of Neolithic pottery were also colored a blackish-gray through this process.

For some Neolithic cultures, ceramics were an important part of the burial assemblage. Members of the Yangshao culture were interred in ceramics urns, which were subsequently buried. Atop these urns, painted basins with elaborate painted images were set. One particularly noteworthy vessel, excavated from Shaanxi Province, had a human face with fish for ears painted on it. Other types of burial vessels were painted with bright colors in elaborate geometric designs.

➤ GOURDS

Many scholars believe that gourds and ceramic vessels were connected in ancient societies since some have similar shapes and were used similarly in these cultures. A gourd is a hollow shell taken from a number of different types of fruit (especially squash and melons). Ancients would dry out these shells and use them as containers. Once dried, they are relatively waterproof and durable, and some varieties look a lot like wood. Unfortunately, in most areas gourds do not survive very well archaeologically, so scholars are left to reconstruct their ancient uses.

—Kevin M. McGeough

Burial pottery associated with the Dawenkou culture sometimes bears incised symbols that some scholars have argued may be an early form of writing. Pottery of the Liangzhu culture also occasionally bore signs, seemingly unrelated to those of the Dawenkou.

The Container Revolution in North America

In an important article, Bruce Smith argued that the introduction of pottery into the eastern woodlands of North America during the period 1000 BCE–300 CE points to more substantial cultural changes than just the introduction of a new technology, a cultural change that he refers to as a container revolution. The use of ceramics by the people of the eastern woodlands suggests a more sedentary way of life, the exploitation of new or different resources, and the use of new production techniques. Along with these changes, it is presumed that the societies of the eastern woodlands became more socially complex during this period, with the emergence of new leaders and new craft specialists. While the introduction of pottery likely did not cause this, it is symptomatic; this is an important clue for archaeologists who are forced to work with very little evidence.

Since pottery is easy to break and inefficient to transport, the fact that it appears in the region around 2500 BCE indicates that the inhabitants were settling down to a less mobile way of life. It is unclear where the first pottery came from, but after 2500 it was locally manufactured.

It is not particularly elaborate pottery. It is rough and gritty, and there was no wheel to allow for very fine forms.

The earliest pots seem to have been designed for transforming wild seeds into edible foods. The seeds would have been crushed and then boiled in these pots. After 2000 BCE, the pottery became more waterproof, possibly for liquid storage. These more waterproof pots may also have been used for the collection of seeds themselves. By submerging masses of dirt into water, seeds will float to the top, and the rest of the material will settle to the bottom. Therefore, rather than trying to pick out individual seeds

by hand, it may have been possible to skim the floating seeds off of the surface.

■ Introduction: Seals, Stamps, and Gems

One of the distinctive technological skills that developed in the time between 4000 and 1000 BCE was the ability to engrave very hard and very small objects in a great deal of detail. Called "glyptic" art, this type of craft was prominent throughout the Mediterranean, the Near East, and the Indus Valley. With most glyptic art, the engraving actually appears as a mirror image on the surface of the object. These objects were meant to be impressed on clay or another malleable medium, thereby impressing the engraved image or writing on the clay. Like a modern stamp, they were tools used to mark other objects.

In Mesopotamia, these small pieces of art are shaped like cylinders with inscriptions that wrap fully around the seal. These cylinder seals were rolled along clay, leaving a continuous image. In Syria-Palestine and Anatolia, stamp seals were more common; these were shaped like a button and engraved on only one side. Egyptian stamp seals are called "scarabs" since the stamp is carved in the shape of a scarab beetle. In the Greek world, stamp seals were common as were gems, engraved stones that were sometimes placed in another setting, such as a ring.

The engravings on the seals varied widely; abstract images, mythological scenes, animal scenes, and written inscriptions were all com-

mon. Written inscriptions typically bore information about the user of the seal, such as name, title, occupation, and ethnicity. Religious motifs or blessings can be informative about the religious values of the bearer as well. Stamps had many functions. One of the most important uses was analogous to the way signatures are used in modern times. They could be impressed onto a legal document as a guarantee that the individual had actually been present when the contract was drawn up and agreed to its terms. They could function as signatures on administrative documents and as symbols of authority. Seals were also used to lock doors: a lump of wet clay was put across the door handle, and the seal was impressed into it. To open the door, one had to break the seal and could not properly shut it again without having the appropriate seal. Jar tops and other containers were also stamped, sometimes with information about the contacts or with information about who sealed the jar. Most seals could be worn; string could be run through small holes, allowing the seal to double as a personal adornment, a marker of status or beauty. In some cases the seals were thought to have magical functions. Scarabs bearing the names of certain pharaohs were thought to be lucky and thus were quite popular.

—Kevin M. McGeough

Mesopotamian Cylinder Seals

Seal cutting was a specialist craft, distinct from other forms of stoneworking. Designs were usually carved into the surface of seals, so they made an impression on clay in which the design was raised and the background depressed, but occasionally seals have the background cut away, leaving the design in relief. The flat surface of stamp seals was relatively easy to carve, but the curved surface of cylinder seals required considerable skill both in layout and in execution. A text of the Achaemenid period stated that a seal cutter served an apprenticeship of four or more years, and a similar period must have been required to attain the level of craftsmanship shown by Mesopotamian seal cutters. The details of the designs and particularly of the inscriptions are so small that they seem to demand that seal cutters employed magnifying glasses, and indeed a polished rock crystal disk with one flat and one convex face found at Nimrud might have been a magnifying lens. Attractive and colorful materials were favored for seals: they varied through time, with steatite, serpentine, and limestone used in the earlier third millennium; lapis employed in some quantity from the mid-third millennium; and jasper, banded agate, and rock crystal coming into fashion from Akkadian times. Haematite was the preferred medium in the earlier second millennium. Carnelian and chalcedony were also used in later times, as was glass.

The art on seals ranges widely in its themes. Among Uruk-period examples are seals depicting a king surveying bound prisoners, people bearing offerings to the temple, contests between bulls and lions, and real and mythical beasts. The skill in the design lay in filling the surface but creating a design that would be equally satisfactory if only a portion of the design was rolled out or if the design was rolled out to a considerable length so that it began to repeat. The Brocade style of the Early Dynastic period fulfilled this by cramming the cylinder surface with small repeated motifs, such as a line of goats surrounded by stars, fishes, rosettes, or geometric figures. Contests between animals or between man and beast similarly filled the space and continued smoothly throughout the seal impression. The modeling on the seals improved, producing

figures that were more three-dimensional. Akkadian seals became less cluttered and increasingly emphasized narrative themes, with the gods frequently shown. Thereafter seal design declined until revived in the later second millennium by the Assyrians, who produced a wealth of vivacious naturalistic and narrative scenes, often featuring animals.

Egyptian Scarabs

The ancient Egyptians used small sculptures of the scarab beetle as amulets and seals. These figurines were both realistically and stylistically carved, but certain features of the beetle were always present: the scarab always stands on an oval disc upon which a text is carved, the scarab itself is represented with a semicircular head and an oval prothorax (the body), and finishes in two side-by-side ovals represent the hard wing cases or elytra. Scarabs were made in a variety of materials: faience, clay, stone, semiprecious stone including carnelian and amethyst, and even gold or silver. Scarabs were often pierced longitudinally, which allowed for the scarab to be put on a string and worn around the neck or mounted on a wire to be worn as a ring.

The scarab beetle was the animal form of the god Khepri, who was one aspect of the sun god. The beetle could be seen rolling balls of dung across the landscape; these balls of dung held the beetle's eggs. Once the eggs hatched, newborn scarab beetles crawled out of it. The Egyptians thought that the scarab beetle died

and was resurrected inside the dung ball. In other words, they thought that the scarab beetle was capable of immortality. The mythological travels of the sun paralleled the scarab beetle's life cycle. The sun was born in the morning, traveled across the sky, and died every evening, spending the night traveling through the underworld, only to be resurrected the next morning. The god Khepri's job as a scarab beetle was to roll the sun disk across the sky all day, but he was also a god revered for having regenerative powers.

Representations of scarab beetles were considered to have magical protective powers. The ancient Egyptians placed scarab amulets over the heart in a mummy as part of the funerary ritual. The heart was not removed when the mummy was embalmed; it was believed to be the seat of consciousness and personality, and a successful journey to the afterlife depended upon its presence. Every dead person underwent a trial where his heart was weighed on a scale in order to determine if the person had lived a good enough life to gain admittance to the afterlife. The scarab amulet was supposed to protect the dead person against evil and lies at his final judgment. The living used scarab amulets as protective charms. In the New Kingdom, scarabs often had prayers inscribed on their undersides. Scarabs were also used as early souvenirs to commemorate important events in the reign of a king.

During the First Intermediate period, the Egyptians started using scarabs as seals. The oval bottom of the scarab was inscribed with a variety of motifs, some decorative (such as interlocking scrolls), others with a hieroglyphic text that could identify the owner of the seal. Those scarabs that had texts on them were usually inscribed with the name of the seal owner, which may or may not have included a list of his jobs (such as mayor and high priest). The seal was impressed in wet clay that was applied to an object or room that was being accounted for. Seals were used to ensure that property such as jars, boxes, bags, baskets, and doors to rooms (storage magazines and tombs) had not been tampered with. Seals were also used to close papyrus documents to prove that the documents were authentic. The king often gave his seal to a person as proof that that person had the authority to act

for the king. As such, the seal represented a system of accountability to the undamaged contents of a box, room, etc.; the authenticity of documents; and the authority of people to act in their office. Scarabs were not the only form of seals used by the ancient Egyptians. Seals also came in a variety of geometrical shapes (shields, rectangles, ovals), representations of animals (lions, hedgehogs, ducks, frogs, fish, etc.), and representations of objects (cowrie shells).

Minoan and Greek Gems and Seals

Minoan and Greek gems and seals are important archaeological finds. Like sherds of pottery, they assist in the dating of archaeological levels, and their well-preserved images are small windows into the living cultures of their time. Furthermore, early Minoan gems and seals are the first tangible proof of a form of European writing.

In Athens in 1893, Arthur Evans came across small three- and four-sided stones, oblong in shape and drilled along the axis. These beads, which appeared to be seals, originated from Crete and were engraved with symbols that appeared to belong to a pictographic system of writing. These bead-seals led him to Crete, where some of the young women wore these brightly colored gems around their neck during the fertile years of motherhood. They believed that the bead-seals had talismanic power to guarantee lactation. The local name for these bead-seals was *galopetres* (milk stones).

In Evans's excavations of Knossos he found large hordes of seals and gems, and on the altars and other votive objects he found hundreds of

clay impressions of the seals, known as sealings. These sealings were also used as ornaments, amulets, and marks of ownership, and they can be found on doors and boxes. In excavations of the Diklaean Caves on Crete, D. G. Hogarth found a sacrificial altar covered with over 6.5 feet (2 meters) of votive offerings, including significant hordes of gems, seals, and sealings.

These large hordes, which had been collected over 1,000 years of Minoan history, can be classified into four distinct periods: Pre-Palace period (2600–2000 BCE), Old Palace period (2000–1700 BCE), New Palace period (1700–1450 BCE), and Post-Palace period (1400–1100 BCE).

In the Pre-Palace period, the seals were made of soft material such as ivory, bone, and faience. They display an amazing array of shapes and designs including geometric shapes such as pyramids, cylinders, and prisms, and they also include abstract shapes of animals, insects, fruit, and sea creatures. Particularly important from this period are the small three- and four-sided stones, which depict the hieroglyphic symbols, the earliest Cretan writing, that drew Evans to Crete. This hieroglyphic writing on the seals has still not been deciphered. The gems and seals of this period are distinctively Minoan, and the patterns cover the entire surface; however, the influence of the Egyptian scarabs and the Babylonian cylinder seal is evident.

In the Old Palace period, the gems and seals differ from the previous period in material, shape, and design. The material is harder, in particular the Cretan steatite, and a few imported semiprecious stones have been excavated. There is less variation in the shapes than in the Pre-Palace period, with three-sided prisms, button shapes, and disk shapes being the most popular. The designs became less geometric, and there is an increase in the depiction of human and animal forms.

The most sublime Minoan gems and seals come from the New Palace period. The Cretan stone steatite is used, but there is an increase in the use of imported semiprecious stones such as amethyst, sard, chalcedony, green and red jasper, agate, sardonyx, onyx, rock crystal, Spartan basalt, and haematite. Some of these seals are partially covered with gold. The carving into these small and hard stones demonstrates the

skill of Minoan craftsmanship. There is a wide range of motifs, which depict detailed scenes. The motifs fall into two main categories: scenes from nature and religious scenes. The religious scenes evolve around a goddess figure often flanked by two animals such as lions or griffins. The scenes from nature include lions, dogs, bulls, insects, birds, and marine life; these motifs depict the abundance of nature. In this same period large gold seal-rings have been excavated, and these engraved seal-rings depict scenes of worship to the Minoan goddess. Many of these seal-rings are extremely large, and the scenes are allegorical in nature.

After the fall and the abandonment of the Minoan Palaces there was a rapid decline in craftsmanship of Cretan art, and there have been few seals and gems excavated in the Post-Palace period. With the lack of organization and wealth after the fall of the Minoan civilization, there was little call for the practice of sealings, and seals and gems disappeared from the archaeological record. They began to reappear in what is now the Greek Mainland and Islands in the sixth century BCE.

Harappan Seals

Thousands of small stone seals of around 2500 BCE with enigmatic script and more than 400 pictographic symbols have been excavated from Harappa. Even though these were the first objects discovered in excavations at Harappa and Mohenjo-daro, the pictographic code has not yet

been deciphered. Some experts believe that these seals could have been used as markers in trade, while others assume that some of these seals might have religious significance.

The usual material for Harappan seals was steatite, a soft stone. These seals were emblazoned with animal figurines or sacred entities. These figures were located in the center of seals, and above them was a short line of Indus script writing. According to one view, these seals were used to stamp clay as a form of trademark for accounting purposes to indicate ownership. Stamped bricks were excavated from the Indus settlements, and the same way of stamping bricks is seen in present-day Pakistan. In another view, people relied on these seals to create protective spiritual amulets.

The seals carried a wide range of motifs. Certain seals show various mathematical formulas and numbers. For instance, the presence of pi confirms the awareness of sophisticated and complex mathematics by these people. Female figurines are also portrayed on these seals with well-designed hair furnished with heavy metal jewelry. This shows that Indus Valley people were rich in art and aesthetics. Some seals have motifs of a man sitting in yoga-like position surrounded by animals, which depict the central and important position of humanity in their cosmic beliefs. Most scholars are agreed that the horned bull that appears on Indus seals should not be recognized as Nandi or Shiva's bull, while elephants adorned on these seals have nothing to do with Hindu beliefs. Osteological evidence proved the absence of horses in Indus Valley civilization before 2000 BCE, and indeed horses are not found on these seals.

Signet ring seals were very common all over Bronze Age West Asia, especially in Halaf times in Syria and in the Tal-i-Bakun phase of southern

Steatite seals from Mohenjo-daro. (Borromeo/Art Resource, NY)

Persia. But it is interesting that Mesopotamian cylinder seals are absent from the Harappan sites. The presence of certain Harappan seals in Mesopotamia also suggests a strong trade and cultural connection between the two civilizations.

■ Introduction: Archaeoastronomy

Archaeoastronomy is best defined as the study of beliefs and practices concerning the sky in the past, and especially in pre-history, and the uses to which people's knowl-

edge of the skies were put. It can be misleading to think of archaeoastronomy as the study of ancient astronomy, since people in the past might have related to the sky in very different ways

from people in the modern Western world. For this reason many people prefer to avoid the word astronomy altogether. Some speak of astronomies to emphasize this point, as is evident in the title of books such as *Astronomies and Cultures*.

Why are archaeoastronomy (and ethnoastronomy) worth doing? If we want to understand more about why certain human communities did what they did in the past, then we need to try to understand aspects of their cosmologies—the ways in which they perceived the world. Astronomy is an essential part of nearly every cosmology, because all human communities have a sky, and the sky and the objects in it form an integral part of the perceived world. The objects in the night sky are immutable, regular, reliable, predictable; for communities who did not live inside brightly lit buildings and whose skies were not polluted by modern city lights, they were there for people to watch and contemplate night after night, season after season. They become imbued with meaning.

The advantage that the sky holds for us in seeking clues about how people in the past understood the world that they lived in is that it forms a part of the ancient environment that is directly accessible to us, unlike things in the terrestrial landscape, which are often transitory. We can use modern astronomy to reconstruct, with considerable accuracy, the appearance of the night sky at any place and time, including the motions of the sun, moon, stars, and planets. And this capability offers a considerable advantage, whether we are concerned with myths and beliefs relating to the sky, monumental alignments upon celestial objects, or other kinds of evidence.

The Earliest Egyptian Astronomical Records—Coffin Lids!

Unlike those of Babylonia, the astronomical records of ancient Egypt, if they once existed, have generally not survived. It is possible that they were recorded on papyrus rather than on clay tablets, as was the Babylonian case. So-called Pyramid Texts, found inside tombs and coffins dating back as far as Old Kingdom times (c. 2600–2100 BCE), and the younger Coffin Texts of the First Intermediate period and the Middle Kingdom, do list various celestial bodies that represent deities, but they are in no way records of observations. Their primary concern is with the passage of the soul to eternal life. The architecture of temples and pyramids in Old Kingdom times gives us some insights into how astronomical considerations affected and determined their construction. However, our main source of information about the development of astronomy and calendrics during Middle Kingdom Egypt comes from wooden coffin lids.

A modest number (about twenty) of such lids survive, dating mainly from the Ninth and Twelfth Dynasties (c. 2160–1780 BCE). Painted scenes preserved on the inside incorporate arrays of hieroglyphs, typically forty rows long by thirteen columns wide. Each box in the array contains a name, and these were, for the most part, repeated along diagonals. The overall effect is of a checkerboard pattern with diagonal stripes, but there are numerous glitches—where a diagonal alignment of symbols jumps by a column, for example.

What was their purpose? The remarkable broad consistency between them, despite individual differences, suggests an elegant answer that makes sense in view of our broader knowl-

edge of ancient Egyptian calendars and clocks. Each box in the grid contains the name of a star or star group known as a *decan*. In a typical table, three rows contain each of the names that appear elsewhere: these are a list of the thirty-six available decans. The remaining thirty-seven rows, containing the nearly diagonal grid, with its occasional glitches, represent the thirty-six weeks of the Egyptian civil calendar—each ten days long—together with the *epagomenal* period of five additional days that made up the year. For any given week, the names reading across the row represent the decans whose rising marked the successive “hours” during the night (these divisions of the night, unlike our hours, varied in length). A week later, each will rise roughly an “hour” earlier, which explains the diagonal pattern. However, since the position of the stars is irregular, it would not have been possible to choose decans that were evenly spaced across the sky, and this helps to explain the glitches.

Although they are often called *diagonal calendars* or *diagonal star clocks*, these were not instruments as such, but arrays of tabulated data. They helped the priest determine the time of night for nocturnal observances. For any given week in the civil year, the user could read off the stars whose appearance in the east would mark a particular hour in the night. We must also bear in mind that the data tables we find on the coffin lids were not actually functional—except, presumably, in the sense that the deceased would take them to use in the afterlife. The tables that actually served as priestly aids have not survived. In any event, each of them must have become obsolete relatively rapidly, because of the slippage of the civil calendar relative to the seasonal year by one day in every four years, and by a whole ten-day “week” after only forty.

The coffin-lid calendars were probably copies of the tables that the priests actually used. It is likely that these copies were made by artists who were not astronomical experts (unlike the creators of the actual tables). Perhaps they made mistakes in the transcription. Indeed, this may well explain other anomalies in some of the coffin-lid tables that do not seem to have an astronomical explanation. Reasonable as this sounds, it creates a headache for the modern interpreter.

Do particular features reflect astronomical reality or were they merely errors in the transcription? To what extent did accuracy actually matter? It is hardly surprising that a definitive identification of all of the decans has eluded modern scholars and continues to do so at the present time.

Astronomy in Egyptian Temples and Tombs

Controversial amongst Egyptologists is the relationship between temples, tombs, and astronomical observations. While most scholars agree that there is some connection between the heavens and Egyptian temples and tombs, there is little agreement on the nature of this relationship. The most obvious clues to astronomical associations of temples and tombs are found in the inscriptions within them. A number of New Kingdom tombs and temples, for example, contain painted “astronomical ceilings,” listing and depicting stars, constellations, and even planets.

But why should these be placed inside tombs? The answer is that ancient Egyptians’ understanding of the sky was framed within a worldview that bound together inextricably the gods, the otherworld *Duat*, the afterlife, and what was

seen in the night sky. It had long been engrained in ancient Egyptian minds that the sun god Ra traveled nightly through *Duat*, the world beyond the horizon, on his journey to the eastern side where the sky goddess Nut would give birth to him once again. Similarly, most of the stars in the sky disappeared from view for a period of some weeks in the year, between their heliacal set and heliacal rise; during this time they too were understood to pass through *Duat*. Likewise, the deceased were required to pass through the twelve parts of the underworld in order to join the gods in the sky. As far back as Old Kingdom times, pharaohs' tombs contained sets of spells known as Pyramid Texts that were designed to ensure a safe passage. Circumpolar stars, on the other hand, were immortal: ever present in the night sky, they never crossed the horizon into *Duat*, never died, and were never reborn. It was these stars that the human soul, striving for immortality, endeavored to join.

These beliefs, and especially the deep importance attached to the north direction with its imperishable stars, may well have given rise to a practice during Old Kingdom times of aligning tombs and temples with the cardinal directions. Pyramids from Saqqara onwards were oriented to the cardinal points, and at the Pyramids of Giza this was achieved with remarkable precision. This practice of cardinal orientation also appears to have been followed, though not necessarily with such great precision, at Old Kingdom temples such as those at Abu Ghurab. Other celestial alignments have also been discovered at Old Kingdom temples and tombs. The great pyramid of Khufu, the largest of the three pyramids at Giza, contains two long shafts connecting the King's Chamber directly to the outside world. Thought for many years to be mere ventilation shafts, it was discovered in the 1960s that one was aligned upon the star Thuban in the north, the closest thing to a pole star at the time, and the other upon Orion's belt in the south. While it is possible that the alignments are fortuitous, it is more likely that they had a very real purpose relating to the journeys to the stars that the pharaoh would need to make in the afterlife.

Various New Kingdom temples seem to have been aligned with the sun. The central axis of

the Great Temple of Amun-Ra is aligned toward winter solstice sunrise. The main enclosure at Karnak also contains several other temples with solstitial orientations. This is scarcely surprising, given that it was the center of a sun cult, but the reasons that particular importance was attached to the winter solstice are unknown. The main axis of another great New Kingdom temple, Abu Simbel, was aligned upon sunrise on (in our calendar) October 18 and February 22. (This temple was moved in the 1960s out of the way of the floodwaters created by the Aswan Dam, but the alignment was carefully preserved.) These dates were probably significant for calendrical reasons, but precisely what these were is hotly disputed.

A number of enthusiasts have investigated possible astronomical alignments at Egyptian temples and tombs over the years, going back to the pioneering efforts of the German scholar Heinrich Nissen and the British physicist Sir Norman Lockyer in the late nineteenth century. Not only solar but also stellar and even lunar alignments have been claimed, but there are inherent dangers in all this. The mere existence of an alignment does not prove that it was intentional, and the number of different structures in each temple complex provides many putative alignments. Only recently have systematic studies of temple and tomb orientations in ancient Egypt, sensibly interpreted in the light of the broader knowledge that has been obtained over the years from a range of archaeological evidence, begun to be undertaken. Preliminary results seem to indicate that temples in the Upper Egyptian Nile valley were predominantly topographically oriented, although some astronomical orientations were included as well, especially upon the winter solstice sun. According to another recent idea, the builders of Old Kingdom pyramids perfected (over time) their orientation and proportions so as to achieve impressive illumination effects at the summer solstice and equinoxes.

Ancient Egyptian Calendars

The kingdom of Ancient Egypt was remarkable in having two different calendars in simultaneous operation. Each arose in response to different social needs and developed a distinct function. At least, this is the standard interpretation of the evidence.

The oldest Egyptian calendar was lunar. It arose in Predynastic times (prior to c. 3000 BCE) from the simple need to keep agriculture in track with the seasons. Twelve lunar phase-cycle (synodic) months only amount to 354 days, so a mechanism is needed for adding an additional (intercalary) month every two to three years in order to keep the calendar in track with the seasons. It is generally supposed that in Upper Egypt (the Nile valley) the calendar was regulated by Sothis, or Sirius, whose first appearance before dawn each year (heliacal rise) coincided with the regular annual flood of the Nile, the most critical event in the agricultural year. Whenever Sothis was not seen until late in the twelfth month, an additional (intercalary) month was added.

Some scholars have argued that a lunar calendar had also developed independently in Lower Egypt (the Nile Delta), but that there it was regulated by observations of the sun. A myth of central importance for the Egyptians was the daily rebirth of the sun god Ra by the sky goddess Nut, who stretched from one side of the sky to the other. This legend was played out in the sky. If the Milky Way was seen as Nut herself, as has been suggested, the legend would doubtless have accounted for its shifting position with respect to the rising and setting positions of the sun, according to the time of year. This would have provided the conceptual basis for what we might too easily see as the purely pragmatic process of keeping track of the seasons by tracking the movement of the sunrise and sunset along the horizon. When the two parts of Egypt became unified into a single kingdom, these luni-stellar and luni-solar calendars would have merged.

The Early Dynastic period (c. 3000–2686 BCE) was the time of the first pharaohs and the development of written records. The lunar calendar was fine for regulating agricultural activity on a local scale but became unworkable for satisfying the needs of a complex economy and state bureaucracy. Recording and regulating the movement of perishable commodities, for example, demanded absolute agreement about the date. Yet the beginning of each month, and the insertion of intercalary months, was determined by observation, and observations could differ; as a result, it was often difficult to be certain either about the month or the day in the month. The result was the development of a quite independent civil calendar used for administration purposes. This comprised twelve “months” of exactly thirty days each, divided into ten-day periods known (rather confusingly, given that the word is commonly taken to mean “ten years”) as *decades*, followed by a five-day period known as the additional or *epagomenal* days, making a total of 365. Once the calendar was set up, it was defined indefinitely; there was no need to regulate it by observations of nature. It was so fit for its purpose that it survived well beyond the end of ancient Egypt itself and was still being used by astronomers in medieval times.

It may seem surprising to suggest that the lunar calendar did not die out when the civil calendar was introduced. Yet this is precisely what has generally been believed for many years, following the work of the great Egyptian scholar R. A. Parker in the 1940s. According to this view, the purpose of the lunar calendar became the regulation of religious observances. Responsibility for determining the correct month and day within this calendar, and with it the timing of religious festivals, became the responsibility of certain priests. At some stage, and possibly as early as Old Kingdom times (c. 2600–2100 BCE), Egyptians started to use the heliacal rise of other stars to help regulate the calendar and to develop the system of *decans*. These were thirty-six stars or star groups whose heliacal risings occurred in succession, roughly ten days apart—in other words, marking successive decades (ten-day periods) in the civil calendar. This meant that the two calendars could easily be synchronized.

Only recently has a different view emerged, proposed by the Spanish archaeoastronomer Juan Antonio Belmonte. This is that different Egyptian calendars did not in fact coexist. In Belmonte's view, sun observations were used initially to establish the 365-day calendar, but thereafter the dates of lunar-related religious festivals were simply established within this calendar, rather as Christians determine the annual date of Easter to this day.

Whatever the outcome of this debate, it is clear that the decans also heralded a hugely important innovation: they could be used as “clocks” to mark the passing of time during the night. Instead of focusing just on the heliacal rise, that is, on the decan rising immediately before dawn, one simply had to view the risings of successive decans through the night. On this basis, the Egyptians were the first to divide the night into approximately equal time intervals. Theoretically, at the equinoxes, when sunrise and sunset are exactly twelve hours apart, eighteen ideally placed decans should rise between sunset and sunrise at intervals of 40 minutes. In practice, however, the length of the night varies through the year, and twilight renders the first and last risings invisible. Furthermore, it could not have been possible to find stars to use as decans that were precisely evenly spaced across the sky. Finally, the Egyptian

kingdom stretched sufficiently far from north to south for latitude to make a difference. The most decans that could actually be seen in one night, during the longest nights of the year around the winter solstice, was twelve. This fact, it is widely believed, led to the concept of the night being divided into twelve “hours,” whose length varied through the year, but which were nonetheless a precursor to the modern concept of dividing the day-night cycle into twenty-four equal hours. There is a scholarly consensus on the identification of several of the decans, but the identification of others remains extremely speculative.

The Egyptian civil calendar was simple, useful, and all-pervasive. It worked unfailingly for almost three millennia, and although it gradually slipped with respect to the seasons (historical sources confirm that the civil new year once more coincided with the heliacal rising of Sirius in CE 139), this never seems to have created a problem during any particular epoch. Not until the third century BCE was any attempt made to add leap years.

Babylonian Astronomy and Astrology

Ancient Babylonia occupies a pivotal place in the history of modern scientific astronomy. In great part this is due to the conscientious nature of the astronomical observations that were made there and the meticulous way in which they were recorded for generation after generation. In time, the existence of a huge, cumulative database of past observations made possible the development of mathematically based rules for predicting future events. The Babylonian legacy of careful observation and recording combined with mathematical modeling went on to influence developments in ancient Greece and beyond. The other reason ancient Babylonia is so important to modern historians of astronomy is the fortunate choice of medium on which many of the ancient astronomical observations (along with many other documents) were recorded. Clay tablets do not tend to disintegrate with time like (say) parchments or papyri and are unaffected by subsequent fire, so they frequently survived the looting or destruction of buildings and other cataclysmic events of history.

Most of the written evidence that comes down to us is in the form of clay tablets from the Seleucid period from 311 BCE onward. Those including astronomical data are of various types: astronomical diaries containing nightly observations; records of sightings of astronomical events such as planetary conjunctions and eclipses; and (increasingly with time) almanacs containing predictions of the length of the month, the positions of the planets among the fixed stars, and many other things. These documents demonstrate beautifully how the systematic accumulation of carefully recorded passive observations led in time to the ability to predict using mathematical models. One thing that made this development possible was the Babylonian system for representing numbers: like ours it used a fixed base, but instead of ten, the base was sixty. In other words, each “digit,” itself a set of strokes representing tens and ones, represented a value

➤ BABYLONIAN ASTROLOGY IN LATER TRADITIONS

Ancient Babylonia was also the birthplace of modern horoscopic astrology, or at least the earliest known example of the belief in the predictive capabilities of charts recording planetary positions at the moment of a person’s birth. (Actually, the horoscopes of modern popular astrology represent a revival of this belief rather than any sort of continuity of tradition.) An important prerequisite was the division of the zodiac (through which the planets move) into twelve regions of equal size. Birth charts began to appear in the second half of the first millennium BCE and represented a move away from the astrologers having to watch the skies passively, waiting for omens to appear, to the more active pursuit (performed on demand) of calculating where the planets would have been among the stars at a particular time. It also represented a shift away from observational astronomy toward intensive mathematics. It is ironic, in view of the way in which modern astrology is seen as the very antithesis of modern science—irrational and unscientific—that this astrological innovation in Babylonian times necessitated making full use of the most up-to-date scientific knowledge and methods that had been developed by this time.

From the late third century BCE onward, two fundamentally different schools of thought emerged for generating predictions from the extensive records of existing observations. These seem to have coexisted throughout the final few centuries of ancient Babylon (until the late first century CE), to judge by two types of works—mathematical ephemerides and almanacs known as Goal Year Texts—that were evidently produced in parallel. The ephemerides represent the height of Babylonian scientific achievement, using sophisticated mathematical models to predict phenomena of the moon and planets with remarkable accuracy. The Goal Year Texts, on the other hand—each one a sort of astrological handbook for a given year—seem to represent an independent tradition of prediction based upon repeating cycles that had been discovered by studying the existing diaries of observations (the Saros cycle was one of these).

—Clive Ruggles

from zero to fifty-nine, with subsequent digits representing “units,” multiples of sixty, multiples of sixty times sixty, and so on. (The Maya, in contrast, used a base of twenty.)

In the Babylonian calendar, the new day began at sunset and the new month began when the thin crescent moon was first sighted in the evening sky after sunset. Back in the third millennium BCE, two calendars seem to have existed in parallel: an “ideal” calendar that was theoretical, with each month containing thirty days, and a common calendar based on actual lunar observations. The first of these calendars is used in early clay tablets that are essentially business documents. This is hardly surprising, since people had to agree on the day something had been signed or a commitment had been made, and this could not be dependent upon the vagaries of whether or not the new crescent moon had been seen (which could be a matter of some dispute, especially if it had been cloudy in certain places at critical times). This civil calendar needed to be the same all over Babylonia and not subject to disputes between different local officials.

Nonetheless, it seems that the actual astronomical calendar (rather than the abstract “ideal” calendar) was used for civil purposes from the second millennium BCE onward, despite the attendant problems. Gradually, the analysis of accumulated observations of first sightings of the new crescent moon enabled Babylonian astronomers to develop mathematical “rules of thumb” that permitted month lengths to be accurately and reliably predicted.

Furthermore, by about the fifth century BCE, the nineteen-month (Metonic) intercalation cycle had been discovered and established. It provided a rule whereby the additional (intercalary) months needed to keep the lunar calendar in step with the seasonal (solar) year could be added in a mechanical, deterministic, yet reliable way. Astronomers no longer had to depend upon independent astronomical observations, such as the heliacal rising of Sirius.

One of the most remarkable consequences of the Babylonian astronomers’ attention to detail and the sheer volume of records that they accumulated over many generations was the recognition of the so-called Saros cycle: it described

the fact that if a lunar eclipse occurs, others will tend to follow at regular intervals of eighteen years and eleven days for many centuries thereafter. This discovery was quite a feat, since approximately forty different Saros cycles run simultaneously, and the conditions for visibility of any particular eclipse vary considerably. Many are completely invisible from any given location on the earth (if they occur during daytime, for example). They simply cannot be revealed by casual observations of lunar eclipses over a few years or even decades, even if clear skies were permanently assured.

In view of its undoubted influence on the development of modern astronomy, it is tempting to view the Babylonian tradition as the birthplace of scientific investigation of the heavens. But this would be highly misleading. The main motivation for the Babylonians’ intense interest in the skies was astrological. Different days in the common calendar were associated with different prognostications, and by the seventh century BCE, scholars were advising the Assyrian king of the calendrical omens. A particular concern was the issue of whether the forthcoming month would have twenty-nine or thirty days. Other concerns included the length of day and night, the heliacal events of stars, the positions of the planets, and of course the occurrence of solar and lunar eclipses. One of the most important series of celestially related clay tablets has become known as the *Enuma Anu Enlil*, meaning “When [the great gods] Anu and Enlil . . .” (the first line of the text). This document, which dates to around the end of the second or the beginning of the first millennium BCE, runs to seventy tablets, and multiple copies exist. It contains around seven thousand omens accumulated from past experience and provides advice as to whether certain celestial configurations and events—signals from the gods—would indicate their pleasure or displeasure.

This was not astrology in the sense that celestial configurations were perceived as the direct cause of terrestrial events (although this did become a widespread philosophy from the fourth century BCE onward in Hellenistic Greece) but rather that they provided portents of events that could then, if necessary, be averted by taking appropriate action. In this, astronomical predic-

tions were used along with a variety of other forms of divination.

Megalithic “Observatories” in Prehistoric Britain and Ireland

All over Britain and Ireland, and particularly in the more remote northern and western areas of Britain and the western side of Ireland, the traveler is quite likely to encounter one of the hundreds—indeed, several thousands—of megalithic monuments (monuments built of large stones) that form a conspicuous legacy of the prehistoric past of the British Isles. Erected in the Neolithic period or the earlier part of the Bronze Age, between the later part of the fourth millennium BCE and the later part of the second millennium BCE, this category of monuments includes huge passage tombs such as Newgrange in Ireland and Maes Howe in Scotland, and spectacular settings of standing stones such as Calanish in Scotland and Avebury and Stonehenge in southern England. It also includes a great many more modest tombs and temples, often found in remote fields and farmlands, as well as stone circles, short stone rows, and many single standing stones. In the mid-twentieth century, the engineer Alexander Thom proposed that many British

megalithic monuments functioned in prehistory as devices for observing the sun, moon, or stars.

Actually, the horizon was the real observing instrument. Given a sufficiently distant horizon, and provided that the observing position is closely enough defined, then any clear, unmistakable horizon feature such as a jagged hilltop or a sharp notch between two steep slopes can be used to pinpoint a particular direction. From the right observing position, the notch or other feature can be used as a foresight marking the rising or setting point of a celestial body to remarkable precision, perhaps to as little as a few arc minutes. For instance, the difference in the rising or setting position of the sun on the solstice and a couple of days earlier or later is normally imperceptible. However, by choosing a suitable observing position and horizon notch, an observer could distinguish the solstice, Thom observed, on the basis of whether or not a brief flash of sunlight from the very edge of the sun's disk appeared in the notch. Many megalithic monuments, he claimed, marked both the place to stand and the direction in which to look. They could, in this sense, appropriately be labeled “observatories.” Classic examples include the stone row at Ballochroy and the standing stone at Kintraw, both near the coast of Argyll, western Scotland.

Thom's ideas of high-precision alignments have not withstood the test of time. During the 1970s and 1980s many problems came to light, including day-to-day variations in atmospheric refraction, and extinction in the case of stars; and many difficulties were found with Thom's selection of data. Many archaeologists were deeply suspicious from the outset of the idea of “observatories” in prehistory. They did not necessarily dismiss out of hand the possibility of deliberate astronomical alignments; what disturbed them was the idea that monumental alignments were used primarily as observing devices. Surely, if the aim was merely to mark a rising or setting position, one could simply use a temporary marker such as a wooden stake, as is done by sun-watchers among the Mursi in Ethiopia. There would be no need to go to all the bother of erecting big stones. Given that big stones *were* used, it would seem more likely that they were encapsulating an alignment that was

➤ “MEGALITHIC” CALENDAR

Sir Norman Lockyer, writing early in the twentieth century, was one of the first to suggest that there was a widespread calendrical practice in Neolithic and Bronze Age Britain and Ireland that involved dividing the year into eight equal parts. This calendrical practice fed through into Celtic times two millennia later, and thence to medieval pagan and Christianized calendrical festivals. It has nothing to do with lunar months but instead involves counting the days from one of the solstices. The eight division points are the two solstices themselves, the two equinoxes, and the four mid-quarter days.

When Alexander Thom started to survey scores of British megalithic monuments several decades later, and to examine their astronomical potential, he noticed accumulations of alignments upon the position of sunrise or sunset at each of these eight dates. There was even some hint of an interest in the dates halfway in between them. On the basis of this evidence Thom proposed that there existed in Neolithic Britain a “megalithic calendar” dividing the year into sixteen equal parts, each twenty-two or twenty-three days long, demarcated by “epoch dates,” which in the modern (Gregorian) calendar would correspond, to within a day or so, to June 21 (solstice), July 14, August 6 (mid-quarter day), August 28, September 20 (equinox), October 13, November 5 (mid-quarter day), November 28, December 21 (solstice), January 12, February 4 (mid-quarter day), February 27, March 22 (equinox), April 14, May 6 (mid-quarter-day), and May 29.

While the sixteen-division calendar never gained wide acceptance, there was a great attraction in the idea that the eight-fold division of the year represented a thread of continuity stretching

through the Celtic calendar and into the even more remote past. Indeed, mid-quarter day alignments have been found among stone circles, such as Beltany in County Donegal, Ireland; among Neolithic passage tombs dating back to the late fourth millennium BCE, such as Dowth (one of the large tombs in the Boyne valley) and Bryn Celli Ddu on the Isle of Anglesey (Ynys Môn) in Wales; and even in one Earlier Neolithic site (a U-shaped setting of timber posts) at Godmanchester in Cambridgeshire, England.

Yet this argument may be circular. There is a distinct danger of our picking out “calendrical” alignments because they seem interesting—because they form part of our list of astronomical targets deemed worthy of attention—while ignoring many other alignments that do not point at calendrical targets. Lockyer was certainly aware of existing ideas about the Celtic calendar, as was Thom. Reassessments of Thom’s data, paying stricter attention to the fair selection of data, have failed to duplicate his results regarding the calendar, as have systematic studies of local groups of monuments. Added to this, the whole notion of a precise “Celtic” calendar, confidently assumed by Lockyer and Thom and their contemporaries, is now known to be highly problematic and questionable in itself.

Finally, one of the other criticisms of Thom’s megalithic calendar was that he did not find calendrical sites as such (although the site at Brainport Bay in Argyll, Scotland, was subsequently claimed as one), but rather a scatter of individual monuments with isolated alignments, each of which indicated sunrise or sunset on just one of the various calendrical epoch dates.

—Clive Ruggles

already well known, perhaps using it for symbolic or ceremonial purposes. This would be entirely consistent with the human tendency, identified by anthropologists, to encapsulate relationships of cosmological significance in monumental architecture. This sort of explanation also fits well with the lower-precision alignments that are more commonly indicated by research in archaeoastronomy today.

Astronomical Alignments in Prehistoric Tombs and Temples in Europe

Scattered through western Europe from Scandinavia and Scotland down to the Mediterranean (and extending into North Africa) are a staggering variety of later prehistoric monuments that still remain conspicuous in today's landscape. Built in some areas as far back as the fourth millennium BCE and even earlier, and in some places only a few centuries before the coming of the Roman empire, many hundreds of great constructions in stone have stood the test of time remarkably well. More modest examples, however, tend to be little known, and many remain under serious threat. Some were tombs, some undoubtedly functioned as temples where sacred rites took place, and some—like the great alignments of hundreds of standing stones at Carnac in Brittany, northwest France—seem to defy explanation. Within this broad custom of constructing monumental architecture were a wealth of local traditions, resulting in groups of monuments as diverse as the recumbent stone circles of eastern Scotland, Irish wedge tombs, Causse-type dolmens of southcentral France, Portuguese antas, Sardinian nuraghi, Menorcan taulas, and many more.

Orientation is a basic and relatively uncontroversial aspect of most of these monuments, in that they have an axis of symmetry and face in some direction. The study of the orientations of these monuments, and in particular of their possible astronomical associations, has been extensive in Britain, Ireland, and Brittany. Indeed, Britain was the birthplace of modern archaeoastronomy, which has resulted in a great deal of attention being lavished on sites such as Stonehenge. Yet, surprising as it seems, there was little or no interest in, let alone large-scale investigations of, monumental orientations in the remainder of western Europe until a systematic survey was undertaken by the British historian of astronomy Michael Hoskin during the 1990s. Hoskin measured and documented the orientations of over three thousand later prehistoric tombs and temples in Portugal, Spain, southern France, and the islands of the western Mediterranean. Within this considerable area and time span one

can identify numerous local traditions resulting in characteristic types of monument broadly consistent in their design and methods of construction. Some occur in large numbers, like the Sardinian *tombi di giganti* ("tombs of giants"), of which over 250 remain; others consist of only a handful of extant examples, such as the *dolmenic hypogea* of the Fontvieille region of southern France, of which there are only four.

The remarkable fact that emerges is that nearly every local group has a discernible orientation signature, as characteristic as the architectural design of the tomb or temple itself. The vast majority of the three thousand monuments face broadly toward the east, southeast, or south. Some local groups cover the whole range from northeast to south, while others fall exclusively within a much narrower span. A few groups of monuments, on the other hand, face predominantly westerly or southwesterly. South-facing groups are rare and north-facing monuments are virtually unheard-of, there being only two examples in the whole set. This shows beyond any doubt that, throughout a significant area of the world and through three or more millennia of prehistory, the orientation of a monument was of almost universal importance—as important, evidently, as the materials used or the techniques of construction. At the same time, it is clear that dominant practices with regard to orientation varied from place to place and time to time just as much as those relating to design and construction. The orientation data give us some clues about how certain practices may have propagated from one region to another. West-facing tombs, for example, are rare in the Iberian peninsula and western and central France, but predominate in the Mediterranean coastal region of France. It seems likely that this practice developed in Provence or Languedoc, where it prevailed, spreading both east toward Italy and southwest toward Spain, but then (in both cases) became increasingly mixed with rival traditions.

It is much trickier to identify the targets that determined a set of orientations, let alone their meaning and significance to the people who built and used the monuments. However, one thing is clear: even the most modest local groups of similar monuments are scattered through a sufficiently large area, and placed in a sufficient

variety of landscape situations, to rule out any suggestion that the determinant was topographic, or even that the orientations were due to factors such as the prevailing wind. We are forced to conclude that reference must have been made to the north-south line defined by the diurnal motion of the heavens. This demonstrates, at least at the most basic level, that reference was made to the skies.

How reliably particular targets, astronomical or otherwise, can be identified for particular groups is debatable. One of the clearest cases is that of the seven-stone antas (dolmens) of central Portugal, where the orientations of all 177 examples measured fall within the sunrise arc on the eastern horizon. A common orientation signature stretches from northeast round to due south, and Hoskin suggests that the motivation here was to orient monuments either in the direction of sunrise or of the sun climbing in the sky. Similarly, some of the westward-oriented groups correspond to the range of directions of sunset and/or sun descending in the sky. An exceptional group of monuments are the taulas of Menorca, whose orientations fall in a range centered upon the south. It is dangerous to try to fit stellar alignments in such a case, since there are many bright stars, and their positions shift significantly over the centuries, owing to precession. However, there is quite strong independent evidence to support the argument that the taulas were associated with particular stars, most notably the Southern Cross and Pointers.

Later prehistoric tombs and temples farther north, in Britain and Ireland, have been much more intensively studied. In some cases, more specific astronomical associations have been identified: for example, the Scottish recumbent stone circles appear to be related to the midsummer full moon. However, taking a broader European view it is clear that their general orientation signatures are very similar to those found elsewhere in western Europe. This implies that more detailed investigation of the monuments in continental Europe may have a great deal more to tell us.

Chinese Astronomy

Many aspects of Chinese astronomy, from ancient times to the later imperial dynasties, are quite distinctive. Some of the earliest Chinese records of astronomical events, for example, are found on divinatory devices known as oracle bones that date to the Shang and Zhou dynasties. These were animal bones or turtle shells heated with a hot needle until cracks appeared in their surface. The shape of the cracks provided prognostications used by kings to assist in affairs of state. Fortunately for modern scholars, the prognostication was recorded on the bone itself, together with the eventual outcome (tending to confirm that the prognostication was correct). Some oracle bones relate to astronomical events, including both solar and lunar eclipses, and form the earliest Chinese records of such phenomena.

In the ensuing centuries and millennia of China's imperial era, the recording of occurrences in the skies became systematized. Yet in China, unlike (for example) in ancient Babylon, a clear distinction was maintained between what we might see as scientific (astronomical) and divinatory (astrological) traditions. The first was predicated on the regularity of calendrical cycles, which could be established through careful observation and recording and then reliably predicted. The latter concerned unpredictable phenomena, which had divinatory significance: these were omens to be noted and acted upon. There were even separate practitioners: experts in calendrical methods and experts in celestial patterns (whom we might choose to categorize as astrologers). Both were highly valued state employees. The goal of the state astronomers, and their principal *raison d'être*, was to produce ever more detailed and accurate almanacs that would reinforce (perceptions of) the emperor's control of order in the cosmos. The purpose of the astrologers, on the other hand, was to warn

the emperor of portents in the skies and aid him in making crucial decisions. Rulers felt they had a mandate from heaven, but if they ignored signs of approval or disapproval and failed to act accordingly, consequences could be dire. The two sets of records—calendrical and astrological—combine to bequeath us an unparalleled data set of observations of astronomical events, both regular and recurrent (such as planetary motions) and transient (on-off), such as the appearance of comets, novae, meteor showers, aurorae, sunspots, and of course eclipses.

Occasionally, a form of celestial phenomenon would pass from the domain of divination to that of calendrics when its underlying regularity was discovered. The classic example of this in the Chinese case is that of lunar eclipses. Around the year 0, the Chinese discovered a cycle of ten years and 334 days (135 lunations), which, like the longer Saros cycle discovered by the Babylonians, defines a period after which a lunar eclipse will tend to recur. With this discovery lunar eclipses essentially became predictable, and while they continued to be recorded, they ceased from this point to have any significance as omens.

A landmark in ancient Chinese astronomy was the development of a distinctive reference system that enabled specialists to map stars, to note the positions of the sun, moon, planets, or transient phenomena, and to reckon time at night. This was the system of twenty-eight *xiu* or lunar lodges. These are best conceptualized as twenty-eight regions into which the sky was divided like the segments of an orange and which were identified by convenient stars and asterisms situated within them. If the *xiu* had been of equal width, the moon would have moved from one to the next in each twenty-four-hour period. However, the widths varied considerably, and the moon could spend two or three nights in a very wide *xiu*, but only a few hours in a narrow one.

Astrology in the Vedas

The religion of the Vedas, which is one of the oldest known in the world, was based on the natural world. This consisted of three worlds: the sky, the atmosphere, and the terrestrial. The sky, which consists of the stars and planets visible to the naked eye, influenced the early Indians to develop an advanced astrological system. This system consisted of a detailed cosmography, a calendar with specific auspicious and inauspicious days, and sky deities. All of these worked together to form the majority of the Vedic religious system.

To understand the religious aspects of the sky, one must first understand the tradition's theory of the universe. In Vedic society, the *risbis*, or learned sages, explained the cosmos as a system of disks, each so large that from a panoramic view they seem as if they are flat. At the center of these disks is the *Bhumandala*, or the sphere of the *devas*, with Mount Meru at its center. Mount Meru is typically referred to in the Vedas seemingly as a mountain within the Himalayan range. Mount Meru is represented in an upside-down conical shape that is 80,000 miles high with the flat top forming the plateau where the pantheon

of sky deities abide, much like Mount Olympus in Greek mythology. With Mount Meru as the center, this forms a geocentric model of the universe with the earth as the focus of the orbit of the universe.

The view of the cosmos in the Vedas formulates the lunar calendar. Within this calendar each month consists of 30 days. According to the *Surya-Siddhanta* (Knowledge of the Sun), there is a corresponding solar calendar from which the days of the week receive their names based on the sun's orbit through the paths of the traditional planets (Mercury-Saturn, the sun, and the moon). Auspicious or inauspicious days were determined by the lunar *rasi* or zodiac. These were determined much like the days of the week: by figuring out which planet the moon's orbit was passing through. The days of the new moon and full moon were considered the best for religious practices. Other auspicious dates for marriages, pilgrimages, and important events could be figured by using the lunar calendar. The 13th day of each lunar fortnight called *Ashtami* was viewed as very inauspicious due to the tension between the sun and moon. Also, any day associated with the planet Saturn was considered quite unlucky and a day on which no venture should begin.

This calendar also dictated the construction of the altar for the Vedic fire sacrifices. The altar would be erected according to the specific deity to which the sacrifice was to be made and in ac-

cordance with the day of the week and month on which it was to take place. Many of these deities, or devas, to whom the sacrifices were offered were manifestations of celestial bodies. Surya, a prominent deity in the Rig-Veda, was an anthropomorphism of the sun. Dyaus was the personification of the sky itself and was possibly the chief deity within the Vedic religious tradition. He is analogous with Zeus from the Greek pantheon. Therefore, all aspects of the fire sacrifice had a tie to the celestial objects.

The objects found in the sky were an integral portion of the Vedic religion, specifying dates for ritual and the gods themselves. They also had an effect on the mundane portion of everyday life from the names of days to the dictation of the proper time to begin and end significant events.

■ Introduction: Engineering and Construction

One of the aspects of life from 4000 BCE to 1000 BCE that moderns often find amazing is the sophisticated construction and engineering feats of societies that lacked access to the kinds of power resources available in later periods. This amazement has led to numerous nonsensical pseudoscholarly arguments that the construction work of cultures such as the Egyptians and Olmecs could only have been achieved by access to some sort of mystical energy or outer-space technology. In fact, there is

no need to presume these kinds of fringe explanations; ancient construction techniques are not as mysterious as they are often made out to be.

For the builders of massive stone monuments such as Stonehenge and the Great Pyramid of Giza, the main power source was a substantial supply of people as a labor force. The main physical limitation on the ability of humans to move objects is the ability for a sufficient number of individuals to grip the object. Often, to facilitate the movement the object to be moved was

placed on a sledge or wagon, allowing it to be dragged along the ground with less friction and more easily by more individuals. The use of ramps and leverage allowed heavy objects to be lifted high above the ground. Animal power could also be utilized to move heavy objects; teams of oxen, for example, could pull very heavy loads although generally quite slowly. Monumental architecture such as that found in Egypt and at Stonehenge point to a high degree of planning, authority, and mathematical skill. The following entries explore some of the specific approaches to ancient construction and engineering from the regions where these ancient skills are best understood.

—Kevin M. McGeough

Construction of the Great Pyramid of Khufu—Giza, Egypt

In the western suburbs of modern Cairo 130 feet above the Nile stands a 1-mile (1.6-kilometer) square artificial rocky plateau called Giza (El-Jizah) by the Arabs. It is the site of three Fourth Dynasty pyramid tombs—Khufu's (also known as Cheops), Khafre's (also known as Chephron), and Menkhaure's (also known as Mycerinus)—named by the ancients among the seven wonders of the world. The largest of them, built at the command of Khufu, has been called a “unique monument” because of its internal disposition. While it is clearly part of an evolving architectural type, there is little doubt that in terms of engineering and logistics, this so-called Great Pyramid was a superlative achievement.

Khufu (Khnum-Khufwy, “Protected by Khnum”) was the second king of the Fourth Dynasty and reigned from 2589 to 2566 BCE. Although little is known of him, he is believed by some scholars to have been a tyrannical and cruel ruler. Whatever the case, clearly he was able to lead and coordinate, because the building of his tomb involved sophisticated social planning to harness an immense team of workers, both on and off the site, together with all the backup resources needed for such a daunting task. The fifth-century BCE Greek historian Herodotus calculated that 100,000 slaves would have taken 30 years to build the Great Pyramid. But it was not constructed by slave labor; rather,

Egypt's peasant farmers, displaced from July through November when their fields were inundated by the annual flooding of the Nile, were deployed on the project as well as on other public works. The cost of their food and shelter (there were workers' villages built nearby) was met from their own surplus production, levied as taxes. Modern scholarship suggests that only 20,000 men could have completed Khufu's tomb in only 20 years.

The base of the Great Pyramid (Akhet Khufu, the “Horizon of Khufu”), oriented within 0.3 minute of accuracy to the cardinal compass points, is 756 feet (230.5 meters) square, covering 13 acres (5.2 hectares). The extensive base means that the tremendous weight of the tall 479-foot (146-meter) building, amounting to an estimated 6.99 million tons (6.35 million tonnes), does not overload the foundation; it is also very stable because its center of gravity is very low. Although of simple design, such an engineering feat challenges even the modern imagination. The pyramid is estimated to contain 2.5 million limestone blocks, each weighing from 3 to 17.7 tons (2.5 to 15 tonnes), rising in 200 steps to the height of a 40-story office block. The joints between the blocks are about 0.02 inch (0.5 millimeter). As originally designed, the pyramid was encased in a layer of polished white limestone 16 feet (5 meters) thick from the quarries at Tura, east of the Nile. Most of it was plundered in the sixteenth century and used to build mosques in Cairo. At the pinnacle of the Great Pyramid there was a solid capstone of polished Aswan granite, standing on a 33-foot (10-meter) square platform.

All this, from quarrying to setting the stones, was achieved with copper and stone tools. Barges were used to transport blocks from a quarry on the far side of the Nile. How were they raised as the pyramid progressed? It is thought that ramped causeways, lubricated with water, were used to haul the sleds; these may have been built at different levels on each side of the pyramid, or a single ramp may have wound around the whole structure as it rose. While oxen were used to move stone blocks in the quarry, the accuracy demanded on-site required wooden sleds hauled by men, and fewer than ten were needed to maneuver a block into place using wooden rockers.

For all the looming size of the Great Pyramid, its interior spaces are relatively tiny. An entrance passage—not the original—connects with a narrow descending passage 345 feet (105 meters) long that leads to a 46-by-27-foot (14-by-8.3-meter) subterranean room, a little over 11 feet (3.5 meters) high. It has been suggested that this was the first location chosen for Khufu's burial chamber; that was quickly abandoned, probably on theological grounds. From the junction of the two passages, an ascending passage 129 feet (39 meters) long leads to the outer end of the "great gallery." From that point, a horizontal corridor gives access to the so-called Queen's Chamber, vaulted with inclined blocks; a second alternative burial chamber, it was never completed and never used. The great gallery, 154 feet (47 meters) long and 28 feet (8.5 meters) high, with a finely crafted corbel vaulted ceiling, leads upward to the final location of the King's Chamber, built of pink Aswan granite. The chamber still contains the huge red granite sarcophagus that must have been put in place while the pyramid was being built. Above it a series of five relieving chambers distributes the weight of the structure above away from the chamber. There are two shafts sealed at the extremities through which the king's *ka* (spirit) could come and go from the underworld.

Several ancillary buildings were associated with Khufu's pyramid. Members of the royal family were buried in mastaba tombs, and three small pyramids to the east were probably for his sister-wife, Merites, and perhaps other queens. Nobles and courtiers were interred in the royal cemetery to the west of the Great Pyramid, where there were also funerary temples and processional ramps. All that remains of Khufu's Mortuary Temple is some of the basalt paving.

Mesopotamian Construction

Houses were generally built of locally available materials, but for palaces and temples, city walls,

and other public buildings the materials, which often included such things as cedar beams, decorative stones, and precious metals, were drawn from a wide area, and the work of their construction would be undertaken by large sectors of the community, including both laborers and specialists such as architects, builders, stonemasons, carpenters, painters, and those skilled in creating inlays. Some of the reliefs in the Neo-Assyrian palaces depict the work of quarrying stone and creating and transporting the huge statues of winged bulls that guarded the palace entrances; texts often detail the materials used and the effort expended in obtaining them, and the records indicate the size of the labor force. The quantities of bricks required for public buildings could be vast. For example, the archaeologist Max Mallowan calculated that the city wall at Kalhu required approximately 70 million bricks, which at the rate of brick-laying recorded in Assyrian times would have taken 700,000 man-days to lay.

Building materials used in Mesopotamian construction varied dramatically depending on the local environment and needs of the community. The nomads who traveled through regions of Mesopotamia dwelt in tents, probably constructed of skins or cloth over wooden poles or branches, but the majority of Mesopotamians lived in houses.

In southern Mesopotamia and particularly in the marshy region around the head of the Gulf, buildings could be constructed of reeds, bound together in bundles and covered with reed mats. Some fourth-millennium seals depict houses or farm buildings of reed bundles, and the rarity of early settlements detected in the region could reflect the widespread use of such structures. Reed structures built by the Marsh Arabs of modern times demonstrate the material's versatility, allowing the construction of substantial and beautiful halls (*mudbifs*).

The most widely available material for construction was mud, which was mixed with straw, dung, or another temper such as sand. This could be simply used as *tauf* (pisé—packed mud) to build house walls but was generally made into bricks. The latter were shaped by hand or formed in molds and dried in the sun. Early bricks were rectangular, but in the Early Dynastic period

plano-convex bricks were made. Shaped like a low loaf of bread, they had the advantage of allowing unskilled laborers to rapidly construct walls by laying them in herringbone courses of alternating bricks on their sides, held in place by liberal applications of mud mortar. Later bricks were generally square.

Bricks could also be fired in a kiln or brick stack. Baked bricks were used for the lowest courses of walls; for drains, where bitumen was employed to make them watertight; and for paved courtyards and other exposed architecture such as the facades of buildings. Important buildings, such as the ziggurat at Ur, might be encased in baked bricks as a protection against the elements. The use of bitumen as a mortar, particularly in the construction of large structures such as city walls, also provided an effective protection against dampness. Courses of reed matting and layers of bitumen were interspersed between those of brick in the construction of ziggurats to counteract rising dampness from the foundations, and weep holes also assisted drainage and prevented decay from dampness. Bitumen was also employed as a waterproofing material for bathrooms and constructional timbers such as doors. Brick walls were often plastered to protect them against rain, using mud or a stronger, more attractive plaster of gypsum or lime. Floors could also be plastered but were often just of beaten earth.

By the later second millennium, bricks were occasionally molded into more ambitious shapes. An early example of this is in the Kassite temple of Innin (Inanna) at Uruk, where walls were decorated with statues of water and mountain deities built up of courses of specially molded bricks, each bearing a section of the design. The glazed low-relief images of dragons, bulls, and lions that adorn the Ishtar Gate and the walls of the Processional Way and the bricks that decorate the throne room entrance at Babylon are the culmination of the technique. Flat glazed ornamental bricks were also found in some Assyrian cities.

Early brick-built temples were strengthened with buttresses, which soon became a decorative feature too, relieving the monotony of the brick walls and creating patterns of light and shade. These were echoed in the interior by re-

➤ DECORATION

Uruk-period temples were often decorated with cone mosaics, geometric designs constructed from clay cones whose flat surface was painted, usually red, black, and white, and that were embedded into the wall plaster so that only the painted surface was visible. In one example from Eanna in Uruk, the clay cones were replaced with cones of colored stone. As well as being decorative, cone mosaics reinforced the surface of these structures, which at Uruk included semiengaged pillars. Using a similar technique, large clay nails with glazed heads were used to decorate the temple of Nabu in the Assyrian city of Dur-Sharrukin.

The plaster walls of buildings could be brightened up by being painted, although traces of these paintings have rarely survived. One exception is the Uruk-period temple at Uqair, where the inside walls were painted with geometric designs and animals, including leopards. Another is the early-second-millennium palace at Mari. Here many of the public rooms had painted decoration: murals showing offerings to the god Sin and the goddess Ishtar in the latter's shrine, the investiture scene in the Court of Palms, and the hunting scenes and other royal activities on the walls of the king's apartments. Paint was probably applied to many of the stone reliefs and statues of Assyrian palaces and to the tiers of ziggurats. These traditionally were colored (from bottom to top) white, black, red, blue, orange, silver, and gold.

Panels of aromatic wood might also decorate the walls of major buildings, or they might be hung with carpets or textiles. Carpets may also have been laid on the floors. In Nineveh, stone imitations of such carpets (beautifully patterned and with tasseled edges) were carved on some of the floors. From the later second millennium external walls were sometimes decorated with glazed bricks, of brilliant blue, orange, green, yellow, red, and white.

—Jane R. McIntosh

cesses. The constraints of roofing using brick also led to the early development of arches, used above doors in houses and tombs, and brick-built barrel or corbelled vaults, seen, for example, in Early Dynastic tombs at Ur.

In northern Mesopotamia where stone was more easily acquired, the foundations and lower

courses of houses and walls were often made of stone. Stone came into more common use in first-millennium Assyria when the brick walls of palaces were clad in stone slabs decorated with low-relief carvings. In the south, where most stone had to be imported, it was less commonly used, but construction in stone did occur. An early example was the Limestone Temple in the Eanna precinct of fourth-millennium Uruk. Another early temple here was built of limestone and a mixture of crushed baked brick and gypsum, which formed a sort of concrete. Some of the tombs in the Ur Royal Cemetery were built of stone. Diorite and other types of stone were used for some architectural elements, such as the sockets in which the door pole turned. Sometimes the bottom of the pole was fitted with a copper or bronze shoe. Limestone slabs were used for paving, such as in Fort Shalmaneser at Kalhu.

Most roofs were constructed of timber beams over which reed mats or palm fronds were laid and then covered with mud plaster. House roof beams could be made from local timbers, such as date palm, pine, and poplar, but for larger buildings such as temples, more massive beams were required. These came from imported trees, particularly cedar from the Amanus Mountains. Timber was also used to make doors, window frames, and other fittings. Cedar, being aromatic, was also favored for constructing palace and temple doors, giving off a delightful scent when used, but for most people and buildings, lesser timbers such as pine and boxwood sufficed. Wooden pillars might support a first-floor balcony in houses, and timber centering could be used to give support to brick and stone vaults.

The Construction of Stonehenge

The magnificent stone circle in southwestern England known as Stonehenge is Europe's most familiar prehistoric monument, and its construction has mystified and challenged archaeologists for generations. The gorgeous setting of Stonehenge on a windy Wiltshire hillside a mile and a half above the river Avon lends to its mystery and allure. Stonehenge dates from approximately 3000 BCE. Archaeologists cannot agree on whether the site was built for sacred purposes such as performing religious rituals or secular purposes such as a solar calendar.

The construction of Stonehenge took place in three distinct stages ranging over a period of 1,500 years, between 3000 and 1500 BCE. In stage one beginning around 3000 BCE, the low earthwork bank and ditch were dug in a circular shape approximately 380 feet in diameter, allowing for an entrance gap in to the northeast. On the site, archaeologists discovered fragments of ancient hand tools such as picks made of deer antlers, scoops made from oxen bones, and pottery fragments. The large circle on the top of a hill might have served as a political meeting place or site of religious offerings, but the northeast entrance implies a connection with the sun's arch at the height of summer. Within the outer circle are found exactly 56 Aubrey Holes, named after seventeenth-century English biographer and antiquarian John Aubrey, who first described their location. The Aubrey Holes are round pits dug two to four feet into the earth and originally held wooden posts.

The second phase of Stonehenge construction lasted 300 years, between approximately 2900 and 2600 BCE. Additional timber postholes were dug within the outer earthworks bank and ditch circle. Archaeologists discovered fragments of wood buildings with a complex pattern of

postholes nearer the center of the circle, but it is impossible to know the size, shape, or purpose of these buildings. With the passage of time, the outer circle ditch began to fill in with rainwater and soil erosion. The ditch as well as the Aubrey Holes were used for the burial of cremated remains, indicating that Stonehenge was a center of religious practice for Neolithic people.

The third phase of Stonehenge construction took place between 2600 to 1500 BCE and saw the import of bluestones from the Preseli Mountains in Wales 250 miles away, in the northwest of England. Ancient architects designed a double crescent pattern for 60 bluestones, weighing up to 8,000 pounds, in the very center of the earthwork and ditch circle. The bluestones range in size, but the average length is six and a half feet.

Around 1500 BCE or about 300 years following the installation of the bluestones, Bronze Age builders began the construction of the sarsen stone inner circle at Stonehenge. Sarsen stones were a type of sandstone and weighed up to 50 tons and were cut from dense rock hills at Marlborough Downs in the Kennet River valley 20 miles to the north. Archaeologists estimate that it may have taken 600 people to drag one of the sarsen stones over that distance and terrain. At the very center of Stonehenge, five enormous trilithons (two upright stones topped with a horizontal stone or lintel) were added. At the same time, 30 additional sarsen stones were arranged in a circle. The original bluestones were moved and rearranged in a horseshoe configuration. Three Portal Stones highlighted the main northeast entrance. The only one of these remaining is called the Slaughter Stone because it was originally upright before tipping over and then sinking deep into the ground. The flat surface of the 21-foot-long stone was imagined by scholars to be used for some kind of ritual slaughter, though there is no evidence for this. Farthest out from

➤ TRANSPORTING ANCIENT STONES

One of the enduring mysteries of Stonehenge is how ancient craftsmen managed to haul large bluestones and sarsen stones distances of up to 250 miles using only human muscle power, rafts, or oxen. One theory posits that bluestones from the Preseli Mountains were brought by rafts along the southern coast of Wales. First, the stones were cut and dragged from the Welsh Mountains and loaded on rafts to travel along the coast and then up the Avon and Frome rivers. From near the present-day city of Frome, the bluestones needed to be carried overland about six miles to reach Warminster in Wiltshire to be loaded on rafts again to reach the site.

The sarsen stones quarried from the Marlborough Downs needed to be pulled or pushed entirely on land because of their enormous size. Hundreds of workers would be needed to pull on ropes made of vines or cowhide and lay wooden rollers in front of the stones as they moved. The whole process probably took as long as one year for each sarsen stone weighing up to 100,000 pounds. To get the stones upright, Stonehenge workers first dug a pit with one upright wall and one wall slanted toward the stone. Wooden poles were inserted to reinforce the pit walls as the stone was levered and pulled into place.

—Jonathan L. Thorndike

the circle is the Heel Stone that is set to align with the sunrise in midsummer.

■ Introduction: Ancient Mathematics

Historians trying to understand the mathematics of other cultures largely have to rely on written sources. What is not written down is not preserved. Mental calculations leave no trace, figures drawn in the sand are soon erased, and computations performed with counters on a board may leave no archaeological record. The history of mathematics is thus restricted to cultures that had writing and is further restricted in scope to what people in those cultures chose to write down. For example, we can understand how some complicated mathematical problems were solved because the solution procedures were written down but not how addition was performed because no ancient scribe thought to explain it in writing.

For the period from 5,000 to 3,000 years ago, the sources are mostly restricted to those from Egypt and Mesopotamia. In both cases, mathematics was the preserve of scribes, who learned it as part of their literacy and administrative training. The sources, however, go beyond the utilitarian. There is much in them that would not be needed in the daily life of a bureaucrat, and there is much in terms of skills and knowledge that would be useful on a daily basis but is not preserved in the texts.

The most common writing material in Egypt was papyrus, which is fragile and decays unless kept in very dry conditions. Very few mathematical texts have survived, and although the large Rhind Mathematical Papyrus displays a wide spectrum of mathematical problems, the paucity of sources means that historians have difficulty delineating the boundaries of Egyptian mathematics. There is also no real chance of understanding how Egyptian mathematics changed over the centuries.

In contrast to the situation in Egypt, scribes in Mesopotamia generally wrote on clay. Once discarded in the ground or even used as building material, clay tablets and the writing on them could survive for thousands of years until excavated by archaeologists. The accidents of archaeology and the fact that many mathematical texts came from unrecorded excavations in the nineteenth century and suffer from a loss of context

mean that there are still large gaps in our knowledge, but it is possible to give a more detailed picture than is the case for Egypt. Additionally, in Mesopotamia, one can trace the development of mathematics from the first writing in about 3200 BCE since there are sources, in greater or lesser abundance, from each period.

—*Duncan Melville*

The Mesopotamian Sexagesimal System

The sexagesimal (base-60) system was an abstract number system developed in Mesopotamia for performing calculations, especially multiplication and division. The sexagesimal system allowed a uniform approach to computation, regardless of size from very large to very small and regardless of the type of quantity being calculated.

Writing developed in Mesopotamia around 3200 BCE as a means of recording administrative information, especially the movement of goods in and out of large organizations such as temples. Along with signs designating what goods were involved, there had to be signs signifying the quantities of goods. The quantity notation used depended very much on the particular type of goods, so that different symbols were used to record a number of sheep, an amount of grain ration, or areas of fields. Within each series, different symbols were used for different-sized units. There were no abstract numbers.

Over the next 1,000 years, these metrological systems evolved and simplified. Toward the end of the third millennium, much of Mesopotamia was ruled by a large centralized state based at the city of Ur. The state kept detailed administrative records and required standardized reporting from scribes throughout its territory, and there were various administrative reforms aimed at simplifying record keeping and computation. At some point during this period an abstract numerical system was born that aimed solely at calculation. The notation used derived from the archaic symbols used to denote discrete goods, a system that had been simplified and expanded

during the intervening time. Actual quantities of goods were still recorded in appropriate notation.

Scribes wrote on damp clay by impressing a sharpened reed. The resulting writing is called cuneiform, meaning wedge-shaped. The sexagesimal system is built out of just two signs, a vertical wedge ∇ for 1 and a corner wedge $\angle$ for 10. Numbers from 1 to 9 were made by bundling the vertical wedges, so 5 would be written $\nabla\nabla\nabla$. From 10 to 59, numbers were made by bundling the 1s and 10s, with the 10s always appearing to the left of the 1s so that 45 would be written as $\angle\nabla\nabla\nabla$. Sixty was represented as a 1 ∇ in the next column to the left (hence the name “sexagesimal” or “base-60”), and larger numbers could be written using the same symbols in place-value notation. For example, $1111 = 10 \times 60 + 8 \times 60 + 3 \times 10 + 1$ was written $\angle\nabla\nabla\nabla\nabla\nabla\nabla\nabla\nabla$. Modern translators write these numbers with commas separating the sexagesimal places, so decimal 1111 is sexagesimal 18, 31. Arbitrarily large numbers can be represented, and the system was also used for sexagesimal fractions, as we write in decimals. For example, $\frac{1}{2}$ is 0.5 as a decimal and 30 as a sexagesimal fraction. The sexagesimal system is a floating-point system; there is no designation of the absolute size of numbers (no equivalent of the decimal point) and thus no notation for empty columns. Thirty and one-half are both written as 30.

A floating-point system is excellent for multiplication and division but not so well suited to addition and subtraction. Mesopotamian students practiced sexagesimal number notation through writing out standard tables. Division was performed by multiplying by the reciprocal so that instead of dividing by 2, multiply by one-half, or 30 (as half an hour is 30 minutes). There were standard tables of reciprocal pairs such as 2~30, 3~20, and so on. Each of these numbers was used for multiplication tables, listing multiples of a given number. Students appear to have worked through the complete set of tables one at a time over a period of perhaps a year and then reviewed by writing out compound tables including several individual tables on one clay tablet.

The advantages of the sexagesimal system were recognized later by astronomers, who need

to do a great deal of complicated calculations, and we still retain the base-60 divisions in minutes and seconds of both time and angle.

Mesopotamian Word Problems

Mathematics in Mesopotamia was learned by scribes as part of their training in literacy and preparation for administrative positions. The best-documented period is the Old Babylonian (ca. 2000–1600 BCE), and it is on this period that we will focus. Scribal trainees began with the basics of making cuneiform (wedge-shaped) impressions on damp clay tablets. They proceeded to learn the signs used in the Akkadian and Sumerian languages, some 600 altogether, and to practice words and phrases. Students wrote out extracts from long lists of words such as names, places, or objects made from wood. In this list-oriented phase they also copied out metrological lists of lengths, areas, weights, and capacities in the various units. Later they wrote out multiplication tables in the sexagesimal place-value system.

In the more advanced stages of the curriculum, students improved their Sumerian by copying extracts from lists of proverbs, hymns, and literature. Advanced mathematics was conveyed by word problems. Before the Old Babylonian period, most identifiable word problems had to do with rations of the areas of fields. Ration problems could be solved using addition and a good grasp of metrology. Determining the area of a field given its length and width was probably done using a good knowledge of metrological conversion ratios. It is still not clear how students solved the inverse problem of finding a side of a field given its area and the length of

➤ FINDING THE CHORD OF A CIRCLE

On a large tablet containing a variety of different problems housed at the British Museum (BM 85194), one problem involves finding the chord of a circle (a line segment with both endpoints on the curve of a circle) using the Pythagorean rule.

A circle of circumference 1. I have gone down 2 nindan. What is the chord? You, (double) 2, you see 4. Subtract 4 from 20, the diameter, you see 16. Square 20, the diameter, 6,40 you see. Square 16, you see 4,16. Subtract 4,16 from 6,40, you see 2,24. What is the square root of 2,24? 12 is the square root, the chord. Such is the procedure.

The problem is to find the length of a chord of a circle that is a distance 2 nindan from the circumference. A nindan was a standard length unit. The circumference is to be interpreted as 1,0 (that is, 60 nindan). The student is expected to know that the diameter of a circle is a third of the circumference (corresponding to setting π to be 3). The procedure generates a rectangle with diagonal equal to the diameter and solves for the chord using the Pythagorean rule.

another side before the advent of the sexagesimal system.

By the Old Babylonian period, represented by some 200 published texts, mathematics had developed to cover a variety of topics, but at its core was a collection of techniques for manipulating lengths, areas, and volumes using multipli-

cation, division, and extraction of square roots via abstract numbers.

Some texts only give the statement of a problem or the statement and the answer. Such texts tell us about the range and scope of Mesopotamian mathematics but not about how solutions were found. Fortunately, some texts do describe procedures. Procedure texts tend to follow a fairly standard format. The problem is set up and the initial data introduced as “I (the teacher) have done such and such.” Then, “You (the student) perform thus . . . ,” and the student is given a set of step-by-step instructions to follow using the specific data from the problem.

Although procedures used the given data from the problem, in many cases it is clear that the algorithms are quite general. In other cases, the data have been tailored to fit the problem. There are a number of texts with collections of problems on related topics. For example, tablet 4652 in the Yale Babylonian Collection (YBC) originally had 22 problems to do with manipulating a stone weight (not all the problems survive), and tablet YBC 7164 has 18 problems on digging a small canal (irrigation was an important part of agriculture). In these cases, the text starts with easy problems and works, often quite quickly, to harder ones.

A large number of problems concern quadratic mathematics, involving lengths, widths, diagonals, and areas. For a long time it was thought that these were essentially algebraic in character. Recently, Høyrup has shown that they can be interpreted in a very geometric fashion. Lengths can be added to areas by the convention of a thick line of unit thickness; pieces of rectangles are torn out and moved around. Squares are literally completed, and finding a square root means determining the side of a square area. Høyrup’s argument is detailed, technical, and complicated but very convincing. Problems involving the diagonal of a rectangle were solved using application of the Pythagorean rule, as the example in the sidebar shows.

Mesopotamian Metrology

Metrology refers to the systems of weights and measures used in a society. The systems vary from place to place and change over time. Understanding metrology requires determining the relationships between the different units in a system and, if possible, comparing ancient units to modern ones. A *sila* in one city at one time may be a different size from a *sila* in another city hundreds of years later, even though the same term is used, and it can be very difficult or impossible to tell whether some units have varied.

The earliest writing in Mesopotamia, dated to around 3200 BCE, is in the form of administrative documents concerning the movements of quantities of goods controlled by large institutions, particularly temples. From these sources it has been possible to uncover the relationships between many of the measurement units. The basic notation for the archaic metrological systems gave each unit a specific symbol. Multiples of the unit were denoted by multiple copies of the symbol until the next unit was reached. For example, in the grain capacity system, a wedge represented the basic unit. Five wedges were represented by a wedge in a different direction. Six of the larger units made a circular impression. Ten circles made a large circle. Three large circles made a large wedge. Ten large wedges made a combination of large wedge and small circle. The systems were specific to the quantities being measured. About 60 metrological signs are known, grouped into about a dozen series. The signs were made by impressing a stylus made from reed onto a clay tablet. There are a limited number of simple impressions to make. Pushing the end straight in gives a circular impression, and pressing at an angle gives a wedge-shaped sign. Similar signs were used in different contexts with different relationships between them.

In the capacity system 6 wedges made a circle, in the discrete system there were 10 wedges to a circle, and in area notation it was 18 to 1.

Over the next thousand years, these complicated notational systems were gradually simplified, and the discrete system, which had units in alternating ratios of six and ten, became used for more and more goods and was the forerunner of the abstract sexagesimal number system developed in the Ur III period (ca. 2100–2000 BCE). In later periods, such as the Old Babylonian period (ca. 2000–1600 BCE), we have abundant evidence for metrological units, not least because trainee scribes practiced writing out long tables of them.

The basic Old Babylonian metrological series measured lengths, areas, weights, and capacity. Relationships between the units are conveniently represented in factor diagrams whereby $nindan \leftarrow 12 \leftarrow kush$ means that there were 12 kush in a nindan.

Length: $danna \leftarrow 30 \leftarrow ush \leftarrow 60 \leftarrow nindan \leftarrow 12 \leftarrow kush \leftarrow 30 \leftarrow shu-si$.

The nindan was about 20 feet (6 meters), giving a kush (cubit) of 20 inches (50 centimeters) and a shu-si (finger) of about 7 inches (17 millimeters) and making the *ush* around 1,181 feet (360 meters) and the danna (stage) about 6.7 miles (10.8 kilometers).

Area: $bur \leftarrow 18 \leftarrow iku \leftarrow 100 \leftarrow sar \leftarrow 60 \leftarrow gin \leftarrow 180 \leftarrow she$

The basic area unit is the sar of 1 nindan², about 387.5 square feet (36 square meters). The iku is about 0.9 acre (0.36 hectare). A bur is an area of length 1 beru and width 1 nindan.

Volume units used the same name as the area units and were equivalent to the area times 1 kush height, so a volume-sar was a volume equivalent to an area-sar times a kush.

Weight: $gu \leftarrow 60 \leftarrow mana \leftarrow 60 \leftarrow gin \leftarrow 180 \leftarrow she$
The basic weight unit is the mana of around 500 grams.

Capacity: $gur \leftarrow 5 \leftarrow bariga \leftarrow 6 \leftarrow ban \leftarrow 10 \leftarrow sila \leftarrow 60 \leftarrow gin$

Capacity was used for measuring grain, beer, and other liquids. The basic capacity unit is the sila of about a liter.

Mathematics in Pharaonic Egypt

Almost all we know about Egyptian mathematics originates from chance discoveries of a relatively small number of documents known as mathematical papyri. These and other sources indicate that mathematics constituted an important part of a scribe's daily work and therefore his education. Only around half a dozen sources are extant, most of which date to the Middle Kingdom (2055–1650 BCE).

However, the beginnings of Egyptian mathematics can be traced back as far as around 3000 BCE to the invention of writing and the number system. Already the earliest written sources indicate that the invention of the number system (and writing) was motivated by the administrative needs of an elite. The mace head of King Narmer (ca. 3000 BCE) provides evidence that the Egyptian number system was fully developed before the First Dynasty (ca. 3000–2890 BCE). It was a decimal system without positional notation with individual signs for each power of ten: a stroke  for 1; a curved sign , possibly representing a hobble for cattle, for 10; a coil of rope  for 100; a lotus plant  for 1,000; a finger  for 10,000; a tadpole  for 100,000; and the seated god Heh  for 1 million. In order to write a specific number, each sign was written as often as necessary (i.e.,  would be 320). On the mace head of King Narmer, a tribute to the king is depicted listing 400,000 bulls, 1.422 million goats, and 120,000 prisoners.

While we have no direct sources from the Old Kingdom (2686–2160 BCE), it has left us many indirect sources indicating the use of mathematics within Egyptian culture. Administrative papyri with ration lists for grain products, meat,

and other items indicate the importance of mathematics in running the Egyptian state. The construction of pyramids, most notably that of King Cheops (2589–2566 BCE) at Giza, must have involved a significant amount of mathematical techniques for the building itself as well as for the necessary logistics (supplies and workforce). However, no concrete information about mathematical techniques of that period has survived. Evidence from administrative papyri and reliefs from tombs representing scenes of daily life indicate the existence of various metrological systems for measuring fabrics, liquids, grain, and other products. Again, the evidence suggests that the creation of these systems was prompted by the administrative needs of the king and the temples.

The first detailed information about mathematical practices can be gained from the mathematical texts that are extant from the Middle Kingdom on. They are written in hieratic, a cursive form of hieroglyphs. The two most important sources are the Rhind and Moscow mathematical papyri.

The Rhind mathematical papyrus was written during the Second Intermediate period (1650–1550 BCE), but its introduction indicates explicitly that it was based on an earlier (Middle Kingdom?) document. It consists, like all Egyptian mathematical texts, of a collection of table texts and problems with their respective solutions. The table texts are lists of mathematical data used in fraction reckoning and metrological conversions.

Fraction reckoning constituted an intrinsically difficult part of Egyptian arithmetic. The concept of fractions evolved from a few simple fractions (i.e., $\frac{2}{3}$, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$), which were written with special signs. On this basis, fractions were conceived as inverses, indicated by what we think of as a denominator along with the hieroglyphic sign for “part” that was placed above it. However, for the simple fractions, their original notation remained in use. What we express as a general fraction was written as the sum of Egyptian fractions (e.g., $\frac{3}{4}$ would be written as $\frac{1}{2} \frac{1}{4}$). The most important table to aid fraction reckoning, the so-called 2:N table, which is found at the beginning of the Rhind mathematical papyrus, indicates the result of the

divisions $2:N$ in the form of Egyptian fractions for $N = 1-101$.

The problem texts first of all teach basic mathematical techniques (e.g., pRhind, nos. 24-29: how to determine an unknown quantity from a given manipulation of that quantity and its result, what we achieve with algebraic equations). The texts also provide the mathematical solutions to practical problems from administration and architecture, for example, the distribution of rations (pRhind, nos. 39-40, 63-65), volumes of granaries (pRhind, nos. 41-46), work rates (pRhind, no. 67), the slopes of pyramids (pRhind, nos. 56-59), and others. The problems are always phrased rhetorically with specific numerical values, and their solutions are indicated in the form of procedures consisting of sequences of arithmetic operations. Arithmetic operations for which specific technical terms were known include addition, subtraction, multiplication, division, doubling, halving, squaring, and the extraction of a square root. Of all these, only multiplications and divisions were carried out in written form using a layout of two columns and splitting up the multiplication and division into steps that could easily be carried out mentally (most frequently doubling but also decupling and others). From the arrangement of problems in the Rhind mathematical papyrus, it can be concluded that its focus was on mathematical practices needed by scribes in their daily working lives. This indicates the educational context of the extant Egyptian mathematical texts: they were schoolbooks and not research papers. Consequently, they give practically no indication about how specific procedures were found or developed.

The Moscow mathematical papyrus is a collection of 25 problems, the first 3 of which are badly fragmented. It contains most notably the calculation of the volume of a truncated pyramid (pMoscow, no. 14) as well as a problem that has been interpreted as the calculation of the surface of a hemisphere, that of a cylinder or that of a segment of a circle (pMoscow, no. 10).

The evidence from these two major papyri is supplemented by several further sources, most of which are only fragments: the Lahun mathematical fragments (UC 32107A, 32114, 32118, 32134, 32159, and 32162), which comprise another copy

of the $2:N$ table as well as several problems and calculations; the mathematical fragment Berlin 6619 (parts of 4 problems); the Cairo Wooden Boards (calculations concerning a grain measure); and the mathematical Leather Roll BM EA10250 (a table for fraction reckoning).

From the New Kingdom (1550-1069 BCE) only two very fragmentary, and therefore insignificant, mathematical texts are extant: Ostrakon Turin and Ostrakon Senmut. However, a large number of administrative texts and some literary texts (most notably Papyrus Anastasi I, a fictional letter from a learned competition between two scribes) from that period indicate that mathematics continued to play an important part in the scribal work life. Evidence from these sources is again mostly unspecific, as the calculations in administrative texts are confined to data and results, and literary texts only give an idea of the uses of mathematics (e.g., to record the harvest) but not of specific mathematical techniques.

■ Introduction: The Natural World, the Human Body, and Medicine

Most scholars identify the origins of biological sciences in the Greek world after 1000 BCE. Yet the people of earlier periods were keenly interested in the natural world and engaged in rigorous study of that world, although their aims and practices varied considerably from the secular science devised by the Greeks. The biological sciences, in ancient Mesopotamia, Egypt, and China, were rooted in careful observations of the natural world and understanding these observations within established cosmological systems. These were sciences of observation, not of experimentation. Fundamental to these sciences was the naming and listing of phenomena. Mesopotamian natural scientists were very concerned with taxonomy and categorization, and the roots of pre-Darwinian taxonomic practices can be found in this time. There are no attested examples of formulations of natural or physical laws, such as those devised by the Greeks. The concerns seem to have been more with identifying each type of bird, animal, fish, stone, plant, tree, or other class of creature and categorizing it appropriately.

Ancient understandings of the human body were not very sophisticated, with a few exceptions. Anatomy was fairly well understood. The Egyptians who practiced mummification knew the structure of the body well, basically dissecting cadavers in order to preserve them. The liver was well studied in ancient Mesopotamia given its use in hepatoscopy, divination through variations in the form of the liver. Medical practitioners from both regions used herbs and drugs to heal the sick, surgery to heal the wounded, and magical incantations in most situations. The Code of Hammurabi details quite severe penalties for doctors who are not successful in healing their patients or who could be considered guilty of malpractice. Chinese tradition holds that internal medicine was developed there concurrently, although there is little positive evidence to support these claims.

—Kevin M. McGeough

The Natural World

The people of Mesopotamia had a good practical knowledge of the properties of clay, sand, metal ores, bitumen, stone, and other natural materials, using them to manufacture pottery, faience, glass, soap, metals, lime plaster, waterproofing, and other useful things. Metallurgy involved scientific skills such as smelting and cupellation; textile manufacture, the chemical treatment of hides and the manipulation of various dyes and mordants; the creation of glass required particular skills and knowledge; and extraction and distillation may also have been practiced. Surviving literature, however, suggests that the Mesopotamians had little intellectual interest in the pure investigation of the physical and chemical properties of materials, which had no place in the school curriculum, and the emphasis in learning was on copying and repetition rather than investigation and inquiry. Technological knowledge seems largely to have been transmitted orally and by example, from practitioner to pupil (and often from father to son). Only doctors, astronomers, exorcists, and other ritual specialists have left volumes of observational data concerning their disciplines. The rare exceptions to this were recipes, for alloying metals, for making glass in various colors, for mixing dyes, and for making perfumes—generally with a colophon urging the initiated reader to keep the information from unauthorized eyes.

The Mesopotamians were, however, deeply interested in the way the world was ordered by the gods. Many different versions of the creation story were current: literary accounts generally included a section on the creation of humanity and the organization of the world. Among the earliest texts, when writing was still in its infancy, are classificatory word lists, which are a form of taxonomy and were to become a regular part of education in school. These divided the world into categories such as domestic and wild animals, birds, fish, trees, plants, and minerals. Within each category the entries were listed in an or-

► MESOPOTAMIAN CARTOGRAPHY

Among the Mesopotamian clay tablets from the later third millennium onward are a number of maps and plans giving designed layouts for houses or temples, with written measurements. A seated statue shows King Gudea with a temple plan and architect's rule on his knees. Others are land survey plans, setting out measured arrangements of fields, with information on the quality of the soil and their current use. One tablet of particular interest shows a scale plan of the city of Nippur, dated around 1500 BCE. It is carefully labeled, with measurements, and shows the city's walls and gates, the river Euphrates and canals, and a number of temples including the Ekur, temple of Nippur's patron god Enlil.

One large area is labeled "garden in the city." Another map gives details of royal and temple properties around Nippur, and there are area maps on which the Euphrates, canals, roads, and a city are marked, including one of the Akkadian period showing mountains and cultivated land near Nuzi and labeled with compass directions.

The most ambitious map ("the Babylonian Map of the World") schematically represents the world as known to the Babylonians around 700 BCE, surviving in a later copy. Two concentric circles surround the mapped area, representing the ocean, and two parallel vertical lines represent the Euphrates, running down to the marshes in the south, which are identified with a label. Another label placed across the river marks the location of Babylon. At the top a semicircle indicates the mountains and around the right side Urartu, Assyria, and Der are named, with Susa at the bottom. Outside the ocean captions identify strange lands inhabited by fabulous creatures.

The "Babylonian Map of the World," showing Babylon, Mesopotamia, the surrounding ocean, and the lands beyond, described in the text at the top of the tablet. (HIP/ Art Resource, NY)

This is the earliest known attempt to map the world.

—Jane R. McIntosh

dered or hierarchical fashion: for example, the body parts started with the head and worked down. Technical terms and chemical substances were also listed. Another popular literary form was the disputation, in which two opposing parties discuss their contribution to a particular activity or field of operation, boasting of their own achievements and denigrating their rival. For instance, Hoe and Plough dispute their relative importance in agriculture; other disputations take

place between Sheep and Grain, Bird and Fish, Ploughman and Shepherd, and Ox and Horse.

Biology was generally written about only insofar as it had a bearing on the accepted forms of scholarship. Animal physiology was studied in minute detail for divination, with attention focused on particular organs, notably the liver. Animal behavior was also relevant to divination. One practical text deals with training horses. Again, it is probable that there was a great body

of knowledge transmitted orally: those who worked with animals, such as shepherds, would have had practical expertise in treating the ailments of their charges, gaining knowledge that was only occasionally recorded in veterinary medical texts.

Language and Lists

By the Old Babylonian period, although Sumerian had become a dead language, it was still an important part of the curriculum. Schoolchildren therefore had to copy and learn long lists of Sumerian words and their Akkadian equivalents; these were also important reference tools for working scribes. The first sign lists showing how to write and read individual signs come from the Early Dynastic period and contained only Sumerian logograms and their pronunciation. Later versions also gave a translation of the Sumerian word: these are known in Eblaite, Akkadian, Hittite, Kassite, Hurrian, Ugaritic, and even Egyptian, and often also showed how to pronounce the Sumerian signs. One major list, which became the main "textbook" in the later second millennium, started in the early Old Babylonian (OB) period as less than 1,000 lines of text but was added to over the years, eventually running to forty-four tablets and having around 14,400 entries. A concise version of this (*Ea A = naqu*) was also used: it had most of the same Sumerian single-cuneiform signs but gave only the main

translation into Akkadian, whereas the complete version (*A a = naqu*—"A pronounced 'a' means complain") listed all known translations. Different forms of lexical lists existed, some dealing with etymology, some with themes, some with phonology, some giving synonyms; one gave standard Sumerian equivalents for *emesal* words and their Akkadian translation. *Emesal* (Akkadian *luru*), was a dialect used in some liturgical works, such as lamentations, and in love poetry: it was apparently spoken by women.

Thematic lists began in the late Uruk period and included the earliest version of what became known as the Standard Professions List. These lists were repeatedly copied, revised, and augmented over the following millennia. Those regularly used included the names of animals, trees, plants, gods, stars, wooden objects, pottery, food and drink, human kinship terms, and many others. The OB canonical version of these lists, *HAR-ra = hubullu*, covered twenty-four tablets and had around 10,000 entries. Originally these were only in Sumerian, but later they were also listed with Akkadian translations; finally, when many of the Akkadian words themselves had become unfamiliar, another column provided an up-to-date explanation of their meaning.

Mesopotamian Medicine

Human biology has not changed significantly in the last 6,000 years, and the peoples of ancient Mesopotamia must have faced many of the same health problems that humans still deal with to this day. We know very little about healing practices in Mesopotamia before about 2600 BCE. Scientific analysis of human remains from the

archaeological record can give some general indication of diet and overall health in the late prehistoric period. Sometimes there is evidence of traumatic cause of death, and skeletal remains and dental wear patterns provide indications of sex, age, and diet. Wear patterns on other bones can indicate stress injuries from repetitive daily activities. There are limits on what we can know about the diseases circulating in ancient Mesopotamia, but paleopathology, the study of ancient diseases, continues to make scientific advances. Material culture from the archaeological record is also illuminating, since certain implements, architectural spaces, and materials in this early period were certainly used for healing. For instance, in third-millennium Ebla in Syria there are indications of a healer using a physician's kit with an array of medical implements, such as blades, tweezers, and needles, among other devices. It is the record of documents inscribed in cuneiform that is Mesopotamia's primary contribution to the study of ancient medicine. These texts describe different types of healers and their methods for reaching a diagnosis based on a patient's symptoms, offering a prognosis for recovery, and using magical and herbal remedies to affect a cure. Herbal treatments of symptoms are common, and many of these were likely effective at alleviating symptoms.

By the mid-third millennium the title "physician, healer" appears. In this same period there are a few magical incantations against illness. Modern scholars often struggle to comprehend the medical texts from this earliest period of writing. Toward the end of the third millennium we find the first real medical prescription, but this is probably merely an accident of archaeological discovery. Mesopotamian medical prescriptions present their own problems, since many of the dozens of plants and minerals named in these texts are now very difficult to match with modern species and geologic classifications.

In some instances letters and literary texts make reference to disease epidemics. Before the advent of epidemiology and germ theory, waterborne or airborne epidemics were devastating and must have been terrifying for these societies to deal with. Other letters contain communications about the activities of physicians and their prescribed courses of treatment.

The view from Mesopotamian texts is essentially that wellness and illness are the products of either divine favor or disfavor, though there also seems to be recognition of some natural causes of illness. The main Babylonian gods of pestilence were Nergal and Erra, and these were identified with the Syrian god Rashap. An angered personal or ancestral god, malicious sorcery, and demonic spirits were all possible supernatural causes of disease.

A number of innovations occurred in the cuneiform documents from the early second millennium BCE. In addition to the developments in mathematics, omen science, and astronomical observation, in the Old Babylonian period (ca. 1900–1600 BCE) medical documents started to include detailed descriptions of symptoms and diagnoses. Medical prescriptions continued to be written in this period as well. A small but important group of bilingual word lists record the names of various diseases in both Sumerian and Akkadian, though these texts may date to a few centuries later.

During the latter half of the second millennium BCE medical handbooks continued to be written and used. An attempt was made in the Kassite period in Babylonia and the Middle Assyrian period in Assyria to organize these large bodies of medical knowledge. For example, the major handbook used for diagnosis and prognosis was edited, and the various symptoms were organized. Following a tradition known earlier in Babylonia, the entries were arranged so that the symptoms proceeded from head to toe.

Two main medical professionals are evident in the second millennium. One figure, known as the pharmacist or herbalist healer, was responsible for producing poultices, tinctures, potions, suppositories, and dressings and may have recited some incantations. The other medical professional, the physician/incantation-priest, seems to have used various handbooks to establish the correct diagnosis and prognosis, and he was also responsible for reciting incantations and performing healing rituals. The practice of surgery was probably limited to very minor procedures and desperate attempts to control traumatic injuries. In any case, the therapeutic texts do not discuss surgical procedures. These specialists and their vast medical knowledge persist in the

➤ COPING WITH ILLNESS IN MESOPOTAMIA—DIAGNOSIS, PROGNOSIS, INCANTATION, PRESCRIPTION

Just as in the present day, in ancient Mesopotamia various physical symptoms were sometimes thought to point to the cause of illness. This cause was usually perceived to be divine or supernatural in origin, as in the following Old Babylonian (ca. 1700 BCE) text.

“If the patient’s hands and feet hurt, nothing stops him from constantly crying out, and his body is not at all warm: it is an attack of witchcraft.”

However, in the same text, there are instances where the diagnosis is unclear, but the prognosis can be determined by specific symptoms alone.

“If the patient’s eyes are bloodshot, he continues to have heart palpitations, and he thrusts out his hand: that patient will not recover. If the patient has a frightened expression, but his face still looks better than when he is healthy: that patient is not healthy.”

The following is an Old Babylonian incantation against a dog bite. The incantation appropriately invokes the goddess Gula, who was associated with both dogs and healing. The ritual illustrates the use of clay to create a model of the attacking animal, by means of which the patient could undo the effects of the dog’s bite.

“Incantation: the goddess Gula lives in the temple Egalmah, and her throne is established there. Her puppies crouch together. A dog leapt up and has bitten a man. The incantation is thus.

Its ritual: you take some clay, and you rub it on the wound. Then you make a model dog with the clay, and you place it on the north wall in the sun. You should then recite the incantation, given above, over it three times, until the clay dog exudes moisture and the man’s bite wound dries up as well.”

In some instances, Mesopotamian physicians would address the specific symptoms with a prescription. The following prescription against incontinence is from the Kassite period (ca. 1300 BCE).

“If a man is sick with incontinence: on an empty stomach he should keep drinking the following concoction with water, all day, for five days: one measure of ashes from a male sheep’s hoof and one measure of ashes from a male *pillu*-plant. He will then recover.”

—Matthew T. Rutz

[Translations by Matthew T. Rutz.]

Mesopotamian record well into the Persian and Seleucid periods in the first millennium BCE. Other specialists were involved with medicine as well. For example, a sick person could consult a diviner, who would use hepatoscopy to determine whether a god would continue to be angry and thus prolong the illness.

A number of symptoms have been identified in Mesopotamian texts. These include many that are familiar to us today: headache, fever, toothache, skin disorders, a crying infant, disorders of the eyes, neurological disorders such as epilepsy, sexual dysfunction, and mental illness. Despite some recent attempts to the contrary, matching clusters of symptoms with modern scientific medical diagnoses is imperfect at best. The sci-

ence and craft of making medical diagnoses is difficult enough in a living, breathing doctor-patient relationship. At such a remove in space and time, the evidence from ancient Mesopotamia, though informative and exciting, should be approached with an appreciation for what we can and cannot know.

—Matthew T. Rutz

Egyptian Medicine

Information on Egyptian medicine comes from a number of sources. Many textual sources, especially the medical texts, have been preserved. Artistic representations also contribute to our understanding of Egyptian medicine. In addition to this, several kinds of nontextual sources are available, including paleopathology, paleobotany, environmental analysis, and dietary analysis.

The diet of wealthy Egyptians would have included a wide variety of foods, including fruits, vegetables, grains, meats, fish, and legumes. Ordinary Egyptians, on the other hand, subsisted primarily on beer, bread, fish, and vegetables. Based on our knowledge of dietary habits, it is possible to generalize about Egyptian health. More direct evidence is also available on this; evidence of both malnutrition and obesity are found in mummies.

Paleopathologic and artistic sources provide evidence of some of the diseases suffered by the ancient Egyptians. Several different kinds of congenital disorders are found: acondroplasia, scoliosis, spina bifida, Spengel's deformity, osteogenesis imperfecta, clubfoot, cleft palate, and hydrocephalus. In addition to these, several kinds of acquired diseases are known to have occurred: tuberculosis (especially of the spine), leprosy, poliomyelitis, cysts and tumors (benign and malignant), gout, ankylosing spondylitis (fusing of the spine), and three kinds of arthritis (septic, osteo, and rheumatoid). Osteophilosis (boney outgrowths on the spine) is frequently encoun-

tered on mummies of persons who died after age 50. Parasitic conditions also existed, including Bilharzia, guinea worm, hookworms, roundworms, tapeworms, and malaria.

Mummies often show evidence of various kinds of physical trauma. Head wounds, some fresh and some partially healed, have been found. Several different kinds of bone fractures also occur, many healed or with splints in situ showing evidence of treatment by a healer. Forearm fractures are particularly common, many of which Joyce Flier suggests resulted while warding off attacks. There is also evidence of successful amputations. Male circumcision was practiced. Dental conditions are also found: attrition (caused by sand in the food), periodontal disease, abscesses, cavities, and hypoplasia.

Collections of so-called medical papyri provide the richest source of information on Egyptian medicine. The earliest of what is traditionally considered the medical corpus, the Kahun Papyrus (1800 BCE), deals exclusively with gynecological conditions. Ramesseum Papyri III, IV, and V (1750 BCE) deal with general ailments including some that are similar to those found in the Kahun. Papyrus Edwin Smith (1550 BCE) contains remedies for trauma and structural breaks as well as for the plagues attributed to the goddess Sekhmet, aging, freshening the house, and one gynecological prescription. The Ebers Papyrus (1500 BCE) deals exclusively with internal diseases of every part of the body and includes over 900 individual remedies. The Hearst Papyrus (1450 BCE) and the Berlin Medical Papyrus (1200 BCE) are almost identical in content to Ebers. Carlsberg VIII (1300 BCE) deals with pregnancy, fertility tests, and eye conditions. The London Medical Papyrus (1300 BCE) contains treatments for bleeding, especially the kind associated with miscarriages. Papyrus Chester Beatty VI (1300 BCE) deals exclusively with conditions of the anus and rectum.

The attribution of modern disease terminology to conditions described in ancient texts is, unfortunately, unreliable and highly problematic. This is due not only to gaps in our lexicographic knowledge but also to Egyptians' own theories of disease, which often differ substantially from our own. From the Ebers Papyrus and those like it, we learn about the *metu*, or vessels,

➤ MAGIC IN EGYPTIAN MEDICINE

Early scholarship regarding Egyptian medicine was guided by a Western bias, which undervalued the intellectual and practical significance of magic to the ancient audience as a component in the treatment of injury and disease. Those aspects that could be made to conform to modern medical science were emphasized. Elements identified (often arbitrarily) as magical were dismissed as superstition. The result was a skewed and incomplete picture of Egyptian medicine. The idea that magic is somehow opposed to true medicine is decidedly contrary to the ancient Egyptian worldview. The combination of what we might consider magical and physical remedies allowed the Egyptian physician to apply the same divine power used by the gods themselves to the practical treatment of earthly ailments.

Healing spells and rituals are first attested in the Old Kingdom and continued to be used throughout Egyptian history. Spoken incantations could be used as remedies either alone or together with amulets or with ingredients to be taken internally. Even when no incantation is present, substances with both physical and magical properties are often found in medical prescriptions. The Ebers papyrus includes general spells to be used to increase the efficacy of any treatment, including those that do not incorporate magical elements.

The ubiquitous application of magic in Egyptian medicine contradicts the traditional categorization of Egyptian healers as either rational surgeons or recipe-hawking physicians. Any Egyptian doctor of mention would have maintained a host of magical remedies in his repertoire of treatments. The priests of certain deities, especially those of Sekhmet and Selqet, were considered to be especially adept at healing. Off-duty lector priests generally served the magical needs of the largely illiterate community, including in matters of health. Egyptian physicians often bore priestly titles in addition to medical ones.

Nonliterate Egyptians could also use magic to aid the healing process. Amulets, especially the udjat eye, were used to protect the wearer from disease. These could occasionally include short spells inscribed upon their surfaces whose ben-

Stele with relief sculpture of Horus as a youth, standing on two crocodiles. He holds serpents and animals, including a lion, showing his power over them. These stelae were intended to prevent attacks by harmful creatures and cure victims of snake bites and scorpion stings. (Werner Forman/Art Resource, NY)

efits would be conferred to the wearer. Household, local, and national deities could be called upon in the form of prayers and votive offerings. From the New Kingdom and later, small stelae known as Horus *cippi* (singular *cippus*) were created that depicted the child Horus triumphant over various dangerous marsh creatures. Water poured over the stele would become charged with the magical power of the spells inscribed upon it, to be consumed by the afflicted individual. This practice enabled one to benefit from the spell without having to actually read it. Originally used for scorpion stings and snake bites, Horus *cippi* were later employed to cure many other ailments.

—Rachel Suvorov

that constitute an all-purpose circulatory system through which blood, air, food, and waste travel. This system could become blocked by *wekbedu*, waste or decay, that could cause disease, aging, and other ailments unless purged from the body. A canal, roughly analogous to the digestive tract, could also become blocked and require purging. Women were thought to possess another pathway that stretched from the mouth to the vagina. Testing whether this canal was closed or open could ascertain conditions pertaining to pregnancy and fertility. The organs were also thought to be capable of moving out of place in the body, such as with the uterus.

Diseases were also thought to result from forces outside of the body, such as plagues that fell under the purview of the lion goddess Sekhmet. Demons and vengeful spirits were feared as agents of disease, a danger to which pregnant women were especially vulnerable due to their risk of miscarriage. Finally, scorpions, snakes, and other noxious creatures indigenous to the Nile Valley posed a constant risk to the health of all Egyptians.

Egyptian medicine employed a wide range of treatments. Structural breaks and trauma, such as those found in the Edwin Smith papyrus, were treated with bandages, splints, sutures, and salves. For internal conditions, a wide range of plants, animals, and minerals were utilized for both their physical and magical properties. Incantations and magical procedures were often used, many times in conjunction with internal remedies. Incantations could also be employed in order to increase the efficacy of any treatment: structural, internal, or otherwise.

The Egyptian physician probably received the same scribal training as other members of the elite literate class. In the Old Kingdom most physicians were priests, but by the New Kingdom fulltime physicians emerged, forming part of a bureaucracy in which some even specialized in various parts of the body. Members of the literate elite were responsible for copying and compiling the medical texts in the House of Life (the temple scriptorium that houses all kinds of texts) as well as making notations as to the effectiveness of various prescriptions.

Egyptian physicians, or *sewnu*, were held in high regard throughout Egypt's long history.

Several instances of foreign rulers requesting the services of Egyptian physicians are attested in the New Kingdom, such as Dushratta king of the Mitanni and Hattusili III king of the Hittites. Greek and Roman writers also referred to Egyptian physicians as skillful and knowledgeable.

Conceptions of the Female Body in Ancient Egypt

The most comprehensive collection of gynecological texts known from the ancient world derive from Egypt. The earliest, the Kahun papyrus (1800 BCE), is entirely gynecological. The Ramesseum papyri III and IV (1700 BCE) contain gynecological prescriptions and contraceptives. The Edwin Smith papyrus (1550 BCE) contains a lengthy prescription for menstrual problems. A large section of the Ebers papyrus (1500 BCE) deals with a variety of gynecological and obstetric problems. Papyrus Carlsberg VIII (1300 BCE) contains birth prognoses. The London Medical papyrus (1300 BCE) contains remedies for miscarriages. The Berlin Medical papyrus (1200 BCE) contains contraceptives and birth prognoses.

A passage, which could open and close, was believed to connect the mouth to the uterus. An opening of the womb was necessary for sex, menstruation, miscarriage, and childbirth; a

WOMEN'S REPRODUCTIVE HEALTH IN ANCIENT EGYPT

While Egypt has by far the most evidence for women's health in the ancient world, most of the evidence reflects concerns about pregnancy and childbirth. There is little evidence for medical care specific to women that is unrelated to reproductive health, and almost no mention of menopause survives. Due to a low life expectancy, menopause may have been a rare occurrence. Great efforts were made to protect the pregnant woman from miscarriage, which was believed to result from stress, injury, demons, or other malevolent forces. Various herbs, spells, and amulets were commonly employed to ward off such threats and seal the womb from danger. Contraceptives were also known and are particularly well represented in Egypt. Certain plants, when taken orally, may have had antifertility effects. Vaginal suppositories could act like a sponge or physically block the opening of the uterus.

—Rachel Suvorov

closed womb protected the fetus during pregnancy but could also cause infertility. Much of the gynecological texts aim to regulate these processes. Birth prognoses attempted to determine whether the passage was open or closed in order to ascertain fertility or pregnancy. One such fertility test was to place an onion in a woman's vagina; if the smell was on her breath in the morning, she was considered fertile. Pregnancy could also be determined by other methods such as urinating on grains, a method whose effectiveness has been demonstrated through modern research.

During pregnancy, menses flowed inside the body and filled up the womb. A premature opening of the womb would cause a miscarriage, and the resulting hemorrhaging was interpreted as menstrual blood. Vaginal injections, spells, and amulets were used to seal the womb against malevolent forces that could cause a miscarriage. Menstrual problems and discharges not related to pregnancy were also treated.

The opening of the womb at childbirth could be aided by spells, vaginal injections, fumigations, and amulets. The Ebers papyrus contains

several passages to loosen a child from the womb or to empty everything from the womb. Generally regarded as the hastening birth or the expulsion of the afterbirth, some are also interpreted as abortifacients.

A number of contraceptives existed that combined physical, chemical, and magical properties. The gum arabic from acacia needles may have been used as a spermicide; Crocodile dung may have been used as a sponge or a magical substance. The infertility that often accompanies periods of nursing was often used to space out pregnancies.

Uterine disease is dealt with extensively in the Kahun papyrus and, to a lesser degree, in the Ramesseum papyri. Symptoms in the extremities are ascribed to disorders of the uterus, which was thought to roam about the body. In addition, the Ebers papyrus contains several prescriptions intended to make the uterus fall to its proper place. Both the Kahun and Ebers papyri commonly employ vaginal injections and fumigations to treat disorders of the womb.

The Mythical Origins of Chinese Medicine

As one of the great contributions that Chinese people have made to the world, the theories of Chinese medicine claim that the human body is an integral whole and that each part of it is intimately connected to other parts. Furthermore, the human body is closely connected to nature.

Disease is caused because of the internal imbalance of *Yin* and *Yang* (the two opposing principles in nature; the former represents the feminine and negative qualities whereas the latter represents the masculine and positive ones) and therefore can be treated by balancing the two elements in the body through the use of such traditional practices as herbal medicine, acupuncture, and moxibustion. Today many Chinese people believe that Chinese medicine can fundamentally put the body into a healthy and harmonious state whereas Western medicine only cures the superficial disease instead of the root cause of that disease.

The most prominent myth about the discovery of Chinese medicine acknowledges the contributions of the practitioner Shennong. Shennong is popularly said to have tasted hundreds of herbs in order to figure out their medicinal characteristics and functions. Then he attained complete knowledge of their flavors and properties of coldness, warmth, mildness, or toxicity, and thereafter used them to cure people's diseases. He once consumed seventy poisonous plants in one day. Sometimes Shennong is described not only as the primogenitor of Chinese traditional medicine but also as a general practitioner of medicine. He is depicted as the first to carefully study the pulse conditions, discern the different characteristics of medicines, and start the therapies of acupuncture and moxibustion. Shennong also wrote a medical book, *Shennong Bencao Jing* (*Classic of Shennong's Materia Medica*), which was attributed to Shennong but

was probably written anonymously around the third century BCE; it was one of the earliest Chinese medical books). Some sources even suggest the sites where Shennong tasted or thrashed the herbs. A text in *Shuyiji* (*A Record of Accounts of Marvels*, written by Ren Fang, 460?–508? CE, chapter 2) states that the tripod caldron that Shennong used to taste medicine could be found on the Shenfugang (literally meaning the “Sacred Cauldron Hill”) of Taiyuan. On Mount Chengyang, there is a place where Shennong purportedly thrashed herbs. The spot came to be known as “Shennong Plain,” and the mountain was sometimes called “Mount Medicinal Herb.” A Taoist temple named Ziyang was built on it. For years it was popularly said that Shennong distinguished the medicinal herbs there.

ERA 3 Classical Traditions, 1000 BCE–300 CE

“Herodotus of Halicarnassus: His inquiries are published here, in the hope of preserving the memory of what men have done and of preventing the great and awe-inspiring actions of the Greeks and the Barbarians from being forgotten and to demonstrate the basis of their conflicts.”

—Herodotus

Sometime before 440 BCE, the Greek historian Herodotus delivered these words or ones like them in the *agora*, or public area, of Athens as the opening to what has become known as *The Histories*. While the Egyptians, Mesopotamians, and Chinese had all recorded information about events that had happened in the past, this work by Herodotus is the first attempt at crafting history in the way that we think of it today. For this work, the title “Father of History” was bestowed upon Herodotus by Cicero, for Herodotus was interested in not just recording events of the past but in trying to understand them as well. In particular, he was interested in the nature of the conflict between the Persians (the “Barbarians”) and the Greeks. In practice, his *Histories* goes beyond that conflict and ventures into the practice of world history, recording and interpreting accounts of the many civilizations located around the Mediterranean Sea and beyond. Even in antiquity, though, his account was not considered trustworthy, and some later ancient scholars referred to him as the “Father of Lies.” Regardless of the veracity of the many details of Herodotus’s *Histories*, this work is a benchmark in historical writing, providing a model of inquiry and evaluation that is fundamental to history writing and a narrative structure that has become typical for the rendering of the past into words. Even our word for history is based on his use of the Greek word for “inquiries” as a description of his work.

Writing slightly later than Herodotus, Sima Qian (ca. 145/135–86 BCE) wrote a history of China from legendary times to his own time and established himself as the father of Chinese history. Like Herodotus, Sima Qian was not interested in merely listing what had happened in China’s past but instead was interested in learning why events had played out as they had. Thus, he abandoned the more traditional approach to writing Chinese history in terms of merely listing chronological events and dynasties. Rather, he presented a general history of Chinese life, often through biography, and organized it into themes, such as music and economics, and in many ways he can be seen as the father of the type of encyclopedia you are currently reading.

What Do We Mean by “Classical”?

The Histories of Herodotus is one of the many works that are deemed “Classics” in the Western canon. In the West, the first and, arguably, most important Classics have traditionally been regarded as the works of Greek and Roman authors that have been judged to be distinguished, among the highest class of writing. Until the mid-twentieth century, these classics were foundational in Western education for at least eight centuries because they were thought to provide models for emulation and to instill senses of honor and correct secular behavior in readers. These works were to be studied and mastered; the reader was expected to strive to understand these writings in depth but not to alter or change them in any way. They were to be preserved in their original form and understood in their original languages and thus evoke a direct continuity to Greek and Roman times.

While in its traditional Western usage the term “Classical” has been applied exclusively to Greco-Roman texts and works of art, it is correctly evocative of the entire era under consideration, the period that lasts from 1000 BCE to 300 CE. For it is not just the ancient writings of the Greeks and Romans that are still read today; during this period, Classical texts were composed all over the world, especially Afro-Eurasia, and this literature, both sacred and secular, still provides profound meaning to much of today’s population. This was the period in which the Jewish and Christian Bibles were created and began to be canonized; Buddhism arose, became a world religion, and articulated its beliefs in a wide variety of sutras, or sacred books; ancient Hindu texts (such as the *Upanishads*) were composed and preserved in their final form; and many of the masterpieces of Chinese civilization were written down. All of these ancient texts have grown beyond their original historical contexts and, as noted, still touch the lives of readers today. For a number of reasons that will be explored in this encyclopedia, people today feel a profound connection with the people who lived between 1000 BCE and 300 CE.

Egypt and Africa

From 1000 BCE to 300 CE, Egypt’s fortunes changed dramatically. It went from being one of the foremost powers in the eastern Mediterranean to a province within the Roman empire. The Third Intermediate period in Egypt began in 1069 BCE and lasted until 664 BCE. Over the course of those 400 years, Egyptian civilization changed dramatically. No longer a culturally and politically unified region, Egypt of the Third Intermediate period was dominated by fragmented local centers of powers and external rulers (from Libya to the west and Kush, or Nubia, to the south). The Late period began in 664 BCE and lasted until 332 BCE. This was the last period of indigenous rule of Egypt until modern times and is often taken as the last resurgence of ancient Egyptian civilization, although there are two points within the Late period in which the Persians occupied the land of the Nile. In 332 BCE, Alexander the Great was welcomed to Egypt, and he absorbed the Nile Valley into his

empire. After Alexander's death, Egypt was ruled by the Ptolemaic dynasty, a Macedonian Greek family. Cleopatra VII, the last Ptolemaic ruler, is famous for her dalliances with the Roman statesmen Julius Caesar and Mark Antony. Egypt's interaction with Rome eventually led to the Roman conquest of Egypt.

South of Egypt at this time in what is now Sudan was the Nubian kingdom of Kush. Nubia had been home to a civilization that stretched back as far (and some argue further) than Egyptian civilization. Around 800 BCE, Kush reasserted itself as a formidable force in Africa, so much so that it eventually took over much of Egypt (and saw itself as the actual bearers of Egyptian culture as opposed to the pharaonic groups to the north). Kushite control of Egypt was not maintained, however, and in 591 BCE the Egyptians invaded and sacked the capital, Napata. After the sack of Napata, power in Kush moved farther south, and by about 300 BCE the dominant center of authority was the city of Meroë. The Nubian kingdom centered at Meroë continued as a powerful African state until around 250 CE, when it seems to have declined.

Part of the reason for Nubia's decline may have been the rise of the kingdom of Aksum (Axum) located to the south, in Ethiopia. Beginning in the first century CE, the city of Aksum and its ports on the Red Sea grew in importance as sailors learned to use the monsoon winds to travel the Indian Ocean. This transportation innovation made the Red Sea an important location in a maritime trade route that connected India, Persia, and Rome directly (and indirectly connected China with the Mediterranean). The Aksumite kingdom became rich, trading African goods (such as gold and ivory) with foreign merchants.

In North Africa, there is evidence for the ancestors of the Berbers. The Berbers were ancient traders who traveled across the Sahara utilizing beasts of burden. Originally these beasts of burden were donkeys, but by the end of this period the traders were using dromedary camels, which were well suited for long-distance travel. Thus, the foundations for long-distance trans-Saharan trade were established. The northern end points of these Berber trade networks were the Phoenician cities located on the Mediterranean coast of Africa, the most famous of which was Carthage. The Phoenicians, who were originally from the coastal regions of what is now called Lebanon, established large colonies throughout North Africa and Iberia that served as important trading centers.

The history of the rest of Africa at this time is not nearly as well understood. From the period 1000 BCE to 300 CE the introduction of iron technology brought important changes to African society. This was an interesting development, since there was only minimal prior use of copper or bronze. Because iron requires such substantial temperatures in order to be smelted, it is likely that this technology was introduced from elsewhere, although Africans undeniably made significant innovations in iron-smelting techniques. In central Africa, especially in the Congo region, there is evidence for early ironworking communities

Cleopatra VII, the last Ptolemaic ruler, is famous for her dalliances with the Roman statesmen Julius Caesar and Mark Antony. Egypt's interaction with Rome eventually led to the Roman conquest of Egypt.

from around the time of the first century CE. Unfortunately, given the current political climate of this region, not much archaeological research is being done there. Similarly, some survey work in Zaire indicates that there were numerous communities in this region in the first few centuries of the Common Era, but little archaeological investigation has actually gone on.

Iron technology certainly played an important role in the continuation of the so-called Bantu Expansion during this period. Bantu speakers continued to spread through Africa, settling in the Great Lakes region of eastern Africa (up to the Indian Ocean) and as far south as present-day South Africa. The newly learned skills of ironworking allowed Bantu speakers to migrate into these less hospitable regions. Bantu-speaking populations also began banana farming and cattle herding although after 1000 BCE. Bantu groups were, in fact, quite culturally diverse and were distributed over a vast geographic area. The Bantu groups that moved into the Great Lakes region developed into centralized polities with significant social stratification. In central and southern Africa, however, Bantu-speaking groups did not develop politically centralized governance. Rather, power was vested in small villages and high-status individuals within those villages, although social stratification and territorial divisions developed as in the Great Lakes region.

Unlike central and West Africa, there seems to have been a high degree of homogeneity among the iron-using cultures of eastern and southern Africa from 1000 BCE to 300 CE. Archaeologists call these cultures the Chifumbaze complex. The pottery of these people is found at a number of sites, ranging in size from substantial villages to small rock shelters, suggesting that the subsistence strategies of these southern Africans were considerably varied. Both farming and hunting-gathering economies are in evidence. In the eastern parts of southern Africa at this time, the dominant subsistence regime was small-scale herding. Unlike the Chifumbaze people, these herders relied mostly on stone tools. The animals they herded were sheep; because sheep are not native to the region, it is likely that these herders migrated from elsewhere in Africa, although this is far from proven.

There is less evidence for the cultures that inhabited West Africa at this time. Best understood is the Nok culture, which was located in present-day Nigeria. Nok terra-cottas are particularly noteworthy, some of which are life-size human figures. Several non-Nok iron-using sites in Nigeria were contemporaneous with the Nok culture, indicating that there were a variety of different cultures inhabiting West Africa in this period.

The Classical World—Greece and Rome

When we think of ancient Greece or Rome, we undoubtedly think of the period from about 800 BCE to sometime after 300 CE in which these two regions flourished as centers of learning and intellectual sophistication. The achievements of Greece and Rome during this time have long been understood as fundamental in the development of European civilization, the birthplace of concepts that are taken for granted

in our own lives. In fact, the Greco-Roman world was only one of many roots of later European civilization, and many of the supposed inheritances may be misconceptions.

By 1020 BCE, the Mycenaean civilization that had characterized much of the early Greek world had vanished. This is not to say that human communities vanished from Greece, for in fact numerous settlements have been explored through archaeology that date to this time, which is otherwise known as the Greek Dark Ages (1020–900 BCE). Rather, life in the Greek world came to take new forms, and while there were certainly inheritances from the Bronze Age, much of what was to come was new. Scholars had initially explained this transformation of Greek life by postulating a “Dorian invasion” or “migration,” a movement of people who spoke Doric dialects of Greek into the south. The historicity of this invasion or migration is debated by scholars today.

At some point at the end of the period between 4000 and 1000 BCE, or more likely within the first 500 years of the period 1000 BCE and 300 CE, the Homeric epics were written down for the first time.

The *Iliad* and the *Odyssey* were initially oral compositions, and much of the style of the written versions that survive today reflect this oral setting (the various uses of repetition, for example). Scholars debate the precise date of the Homeric epics’ oral composition(s) as well as the dates of the fixing of the traditions in writing. Scholars likewise question the historicity of Homer, the supposed single author of the epics, suggesting that the recording of these compositions may have been more complex than one individual simply writing down an oral composition. Whatever the case may be, the Homeric epics (in various guises) were one of the unifying features of the Greek world.

Scholars likewise question the historicity of Homer, the supposed single author of the epics, suggesting that the recording of these compositions may have been more complex than one individual simply writing down an oral composition.

Around 900 BCE, at the end of the Dark Ages, there was probably not a drastic change in the way in which the Greeks had lived their lives, but there was a change in evidence discernible to archaeologists. This evidence was manifest in pottery, first discovered in Athens, that archaeologists call “Geometric,” and thus the period from 900 to 700 BCE is referred to as the Geometric period. By about midway through this period, it is apparent that the polis, or city-state, has come to be the dominant organizing polity of Greek civilization, and this remained the case until the conquest of Greece by Alexander the Great. Throughout the Geometric period, Greek populations grew and prospered, and colonizing movements began in Italy and Asia Minor. The number of Greek colonies in southern Italy was substantial, and this region came to be known as Magna Graecia (Great Greece). Colonies on the Ionian Coast of western Anatolia were more numerous and spread Greek influence to the Near East. By the end of the period, Near Eastern influence on Greek culture had become profoundly influential. One of the cultural elements in which this contact was manifest was in ceramic artistic styles, and thus the period from approximately 700 to 600 BCE is called

the Orientalizing period, reflecting the Near Eastern influence on Geometric pottery styles.

Much of this contact in the Orientalizing period came about through a fluidity of movement in the eastern Mediterranean. The Greek colonies that had been established in Ionia brought Greek populations into close contact with the peoples of the Near East. The Phoenicians (whose homeland was in northern Syria) established colonies in the western parts of Greece and Crete. The establishment of Greek colonies in Italy and Sicily not only spread Greek culture westward but also brought Greek and Phoenician cities into closer proximity with one another. Renewed Greek contact with the Near East in the Orientalizing period led to important developments within the Greek world beyond just changes in pottery. Greek artists who worked in other media incorporated Near Eastern aesthetics (especially Phoenician aesthetics, themselves adapted from Egyptian aesthetics) into their own art, and some Near Eastern literary and mythological themes may have been reinterpreted in light of Greek practices. For example, Greek kouros are statues of human figures that bear a striking resemblance to Egyptian sculptural art. Near Eastern technological knowledge, such as metallurgy and textile manufacture, was introduced to the Greeks, as was Near Eastern knowledge about astronomy/astrology and divinatory practices. Coinage was introduced to Greece by way of Lydia, making trade transactions significantly easier. The Greek alphabet emerged during this time, adapted from the Phoenician alphabet (itself adapted from an alphabet attested in its earliest form by Semitic speakers in the Egyptian desert).

The Near East was not the only region that came into contact with Hellenic civilization at this time; Greek colonies were the intermediaries of trade between the Mediterranean and peoples of inland Eurasia. Greek luxury goods have been found as far away as Russia and Bulgaria, and while this contact may not have been direct, the desire for Greek objects stimulated long-distance exchange. Cultures, such as the Etruscans of Italy who lived in close proximity to the Greek colonies to their south, adopted many Greek customs and material culture. The Greeks may also have adopted some elements of these inland Eurasian cultures. The ancient Greeks certainly believed that the worship of Dionysus originated in Anatolia or Thrace (mostly present-day Bulgaria), although the fact that the name “Dionysus” exists in Mycenaean tablets suggests that this may be incorrect.

The Greek colonies in Ionia (central coastal Anatolia in present-day Asian Turkey) did not just adapt Near Eastern traditions into Greek forms; they were themselves locations of artistic and intellectual fluorescence. Ionian art at this time laid the foundations for a naturalist approach that would come to typify Greco-Roman art. The sixth-century philosophers at Miletus in Ionia were the first Greek natural philosophers. Indebted in some ways to Near Eastern approaches to science, the Ionians attempted to understand the physical universe and laid the foundations for Greek science.

The period from about 600 to 500 BCE is called the Archaic period, and this is the beginning of the Classical period of Greek history. From

the Archaic period until the middle of the fourth century BCE, Greek life was organized primarily by the polis. While these cities would join together in alliances (especially against the Persians) or war with one another, there was rarely an overarching governmental structure. Athens from the fifth century on was the birthplace of many intellectual achievements and home to some of history's intellectual giants: the philosophy of Socrates, Plato, and Aristotle; the art of Phidias; the histories of Herodotus and Thucydides; the plays of Sophocles; and the democracy of Themistocles and Pericles. Yet at the same time that the arts, sciences, and democracy were thriving, Athenian life was based on systemic inequalities against women, slaves, and foreigners, especially non-Greeks. Sparta, another prominent city-state, was a militaristic society, dominated by a strong sense of discipline and desire for structure in life. Other poleis (the plural of "polis"), such as Corinth, Thebes, and Syracuse (in Sicily), were noted centers of artistic and intellectual activity whose influence within the Greek world waxed and waned throughout this period.

As the Greek city-states fell into political disarray, a peripheral Greek state rose to power. Macedon, located in the northeastern corner of the Greek world, was led by Philip II (r. 359–336 BCE), who had steadily expanded his empire and become more involved in the affairs of the Greek city-states, unifying many of them under his own authority. In 336 BCE he was assassinated, and many of these states rebelled. His son, Alexander, who is remembered as Alexander the Great, became king of Macedon and not only gained control of the rebelling states but also went on to invade Egypt, Syria-Palestine, Persia, and even northwestern India. Alexander and his successors spread Greek culture, languages, and institutions and mixed together many disparate cultural elements into a cosmopolitan *ecumene* (a Greek word meaning "household" that has come to mean an interconnected and cross-fertilizing entity of various cultures). This new blending of cultures, which had a profound Greek overlay, has come to be known as the Hellenistic world (as opposed to the previous parochial Hellenic world centered on poleis). In 323 BCE Alexander died unexpectedly, and his vast empire (the largest in history up to that point) was, after much conflict, divided among the Diadochi (his successors): the Antigonid dynasty gained Macedonia and Greece, the Seleucid dynasty controlled Mesopotamia and Persia, and the Ptolemaic dynasty took Egypt and Palestine. While these dynasties fought and competed with one another, eventually all of them were absorbed by the Roman empire.

Despite the political turmoil that at times typified the Hellenistic Age, the cultural interchanges that occurred were of world historical significance. This was a true merging of cultures from around the eastern Mediterranean, the Near East, and farther into Southwest Asia. Greek became the lingua franca of Hellenistic society, although local

Alexander and his successors spread Greek culture, languages, and institutions and mixed together many disparate cultural elements into a cosmopolitan ecumene (a Greek word meaning "household" that has come to mean an interconnected and cross-fertilizing entity of various cultures).

languages were not completely displaced. Especially among elites in the Near East, hybrid cultures (mixtures of Greek and Near Eastern elements) arose. Negotiations about which foreign cultural elements to accept and which should be rejected created tensions within communities. The Jewish text, *The Wisdom of Ben Sirah* (or *Ecclesiasticus*), exemplifies these kinds of cultural interchanges. The text is written in a typically Near Eastern genre called wisdom literature in which advice is given by the author. In Ben Sirah's case, his wisdom is clearly informed by Greek philosophy, yet at the same time he warns against the adoption of certain Greek practices, such as the use of the gymnasias.

The cultural interchanges that typified Hellenistic society did not just involve the transmission of Greek practices elsewhere. Near Eastern and Southwest Asian culture also spread into the Greek lands, and Eastern practices were adopted as Greek. The city of Alexandria, founded on the Mediterranean coast of Egypt, became something of a cultural (not political) capital of Hellenistic society. The famous Library of Alexandria is said to have held over 700,000 volumes, writings collected from the Near East and elsewhere. The learning of the Greeks is referenced positively in Indian texts; the *Mahabarta*, for example, praises Greek scholars as "all-knowing."

Unlike Greek history, the history of Rome begins as the history of one city and traces the expansion of that city's power throughout the Mediterranean world. Scholars debate who were the cultural precursors of the Romans, but undoubtedly Etruscan civilization, which flourished from about 800 BCE to after 300 CE, was an important influence (which was incorporated politically into Roman society well before 300 CE). Etruscan society was itself heavily influenced by Greek culture, even adopting the alphabet from the Greeks. Tradition holds that Roman history began on April 21, 753 BCE, when Romulus supposedly founded the city of Rome. While it is unlikely that Romulus was an actual king or founder of Rome, 753 BCE is taken as the beginning of the Regal period, and Romulus is counted as the first king. After Romulus, tradition holds that six more kings ruled Rome, although historians debate which of these kings were historical figures. Some have argued that this was a period of Etruscan dominance, but scholars debate this. The Regal period lasted until 509 BCE, when the king was expelled and an oligarchic republic replaced the monarchical form of government.

The period of the Roman republic lasted for about 500 years, until Augustus seized sole authority, and the state became an empire after 31 BCE. Throughout the republican period, Rome was governed as an oligarchy by a number of legislative bodies. From the earliest days of the Republic, Rome warred with its neighboring cities, gradually conquering them and either incorporating them directly into Roman society or making them unequal allies. By 272 BCE, Rome gained control of all of southern Italy. After cementing authority over Italy, Rome was drawn into conflicts with the Greeks and Carthaginians (in Sicily, Iberia, Gaul, and North Africa). As the Romans expanded into Greek territory they brought much of Greek culture back to Italy, although not all Romans approved of this Hellenizing process (Cato the Censor, for example, warned that Greek culture was contaminating Roman morality and val-

ues). Greek culture, literature, and theater were adopted in Rome and adapted to suit Roman tastes. Roman attitudes toward Carthage, however, were less deferent, and after the Second Punic War (218–201 BCE), the Roman populace favored a militarily aggressive stance toward Carthage, which led to the Third Punic War (149–146 BCE) and the destruction of Carthage.

As Rome grew in power and wealth, its Republican governing structure became too unwieldy. Disparities in wealth exaggerated these problems, as did the power struggles among prominent men and families. The ruination of large numbers of farmers due to costly wars and their subsequent movement into the city of Rome also strained the Republican political system. The end of the Republican form of government was foreshadowed when Julius Caesar took power as dictator, although the Senate assassinated Caesar to stem this power. This return to Republican governance was short-lived, and eventually Augustus, after defeating Antony and Cleopatra at the Battle of Actium (31 BCE), became emperor and the sole ruler of Rome.

After Augustus's death the imperial period began, typified by political authority being held in the hands of one man. Under the emperors, Rome's influence expanded into Europe (up to the Rhine, Danube, and Scottish lowlands), into Southwest Asia, and across North Africa. Where the Romans went, they brought with them Roman culture. Roman construction was unparalleled, and Roman cities were built according to a similar plan throughout the empire. Scholars refer to this process as "Romanization." Aqueducts provided the cities with extensive water supplies, and roads and naval paths connected the different ends of the empire with a thoroughness that had never before been achieved. Roman theaters (adapted from Greek designs) and amphitheaters are still used today in Jordan, Israel, France, Germany, and elsewhere in Europe and North Africa.

It was not just "Roman" culture that was spread with Rome; the expansion of the Roman empire continued the expansion of Hellenistic culture and the transregional tendencies of Hellenism. The Romans brought Hellenistic ideas (or at least Roman versions of these ideas) to the farthest regions of the empire and to people who lived outside of the boundaries of the empire, such as the Celts in Gaul and Britain and the Germanic tribes north of the Rhine and Danube. Roman thinking was heavily dependent on and in many ways grew out of Hellenistic thinking. Roman literature, for example, while initially dependent on Greek forms, blended Greek styles with Roman ideas. Virgil's *Aeneid* took the traditional Greek story of the Trojan War and recast it as a means of understanding the foundation of Rome.

Rome's reach was felt far beyond the boundaries of its territorial empire. Trade connected the Romans with more distant regions of Asia and Africa. Via the Red Sea, Roman traders traveled back and forth from Syria to India, encountering the Ethiopian Aksumite empire along the

Roman literature, for example, while initially dependent on Greek forms, blended Greek styles with Roman ideas. Virgil's Aeneid took the traditional Greek story of the Trojan War and recast it as a means of understanding the foundation of Rome.

way. The hunger for spices in Rome drove the profitable trade of the Nabataean kingdom across the string of oasis that traversed Arabia. The Nabataeans were eventually conquered by the Roman emperor Trajan, and their previously distinct culture was absorbed into Roman culture. Rome was also the westernmost of four great empires that spanned Eurasia, connected by the Silk Roads. Along with the Parthian empire and later the Sassanid empire, the Kushan empire, and China, Rome participated in a vast exchange of goods and ideas. Pliny the Elder (d. 79 CE), for example, tells us of the mania among Rome's women for silk from the land of the Seres, attesting to the importance of these distant connections.

Romanization was not just a unidirectional flow of ideas; Roman culture was itself influenced by the interchanges of ideas across Afro-Eurasia. The Parthians, who were often rivals of Rome, influenced Roman policies of imperial expansion in the East and perhaps influenced the development of Roman court politics and the organization of power structures under the emperor. Likewise, religions of the Near East were very popular among the Romans. Some of the mystery religions (so-called because participation in the cults was reserved for initiates) were Eastern in origin, although the Eastern pedigree of these religions was sometimes exaggerated in Rome to give them an antique mystique. Mithraism (the mystery religion devoted to the god Mithras) likely originated in Persia. The worship of the Egyptian goddess Isis was popular throughout Roman society, as was the worship of the Anatolian deity Cybele. The Eastern religion of Christianity, while not a mystery religion, grew in popularity within Roman society in part due to the relative safety and ease of travel for Christians within the Roman sphere of influence. These Eastern religions were also spread by Roman soldiers to the peoples beyond the Alps, setting the stage for the later spread of Christianity throughout Europe.

The Near East

The period from 1000 BCE to 300 CE saw the rise of the kingdom of Israel and the concomitant development of Judaism and Christianity. Scholars debate the extent to which the biblical narratives (found in the books of Samuel, Kings, and Chronicles in the Hebrew Bible/Old Testament) reflect historical circumstances. The biblical account suggests that the kingdom of Israel formed into a monarchical state around 1000 BCE and divided into two kingdoms (Israel in the north and Judah in the south) in 922. Eventually both kingdoms were destroyed and incorporated into larger Mesopotamian empires. Part of this incorporation involved large-scale population deportation, and many Israelites found themselves living in Babylon after 586 BCE, when the Neo-Babylonians destroyed the Temple in Jerusalem. This exile was short-lived but important. The experience of living in exile and encountering other traditions (such as Zoroastrianism) may have played a significant role in the development of the impulse to collect the various writings of the Israelites into one set of works; this set of works would eventually become

the Tanakh, or Hebrew Bible. After the Persians conquered Babylon in 539, many of the Israelites were allowed to return to Jerusalem. By this time, the Israelites had started to think of themselves as Jews and monotheists, bound together by their religious beliefs and cultural heritage. Many of the large number of Jews who did not return to the land of Israel maintained their identities as Jews, a situation referred to as the Diaspora.

The Jews who did return to Israel were allowed to rebuild the Temple and institute local governance due to the tolerant imperial practices of the Persians. Eventually this region was conquered by the Romans and directly incorporated into the Roman empire. Under Roman rule, divisions among various groups of Jews developed over a number of different matters. One of these groups abandoned Jerusalem to live at Qumran near the Dead Sea. It is likely that this group compiled the Dead Sea Scrolls, although this is debated by Scrolls-scholars. Another Jewish movement that developed at this time was Christianity, based on the teachings of Jesus and his later followers, especially Paul. From 66 to 73 CE, the Jews revolted against Rome. The Romans responded by destroying the Temple in Jerusalem. The destruction of the Temple, while a devastating event in Jewish history, played a large role in the development of Rabbinical Judaism and the synagogue as the primary location of Jewish worship. The first synagogues can be dated to this period. The oral teachings of the early rabbis living in Israel were written down around 200 CE in the Palestinian (or Jerusalem) Talmud. Written in Hebrew and Aramaic, this collection of rabbinical notes about the Bible reflects the debates and teachings of rabbis from about 70 to 200 CE. The larger and more influential Babylonian Talmud, written by the Jewish community that lived in Mesopotamia, was not edited into its current form until about 300 years later.

Whereas Judaism was transformed and survived during this age, this was the last period of Mesopotamian civilization, located in what is now called Iraq. By 1000 BCE, the Neo-Assyrian empire, centered in the north of Mesopotamia, was one of the largest powers in the Near East. At its maximum extent, the empire included all of Mesopotamia and much of Anatolia and Syria-Palestine. In the seventh century BCE, Assyrian control over the south started to wane, and Babylon began to rise as a power, supported by its ally, the Medes, located in what is now known as Iran. Eventually Babylon conquered Assyria, and the Neo-Babylonian empire (sometimes referred to as the Chaldean empire) expanded almost as far as Egypt.

The Neo-Babylonian empire did not survive long. In 539 BCE, the Persian empire (also known as the Achaemenid empire after its dynastic founder) conquered Babylon. Based in Iran, the Persians had recently risen as a major regional power, and they quickly gained control of the Neo-Babylonian territories. Persian rule over foreign regions was relatively mild, and they were content to let local regions govern themselves so long as tribute was paid. Despite this relatively benign attitude toward rule, the Persian attempts to expand into the Greek world were halted. The wars between the Greeks and the Persians are well documented in ancient sources, most notably in the works of Herodotus and

Aeschylus who, not surprisingly, provide a Hellenic-centered account of these conflicts. Eventually, Greek power eclipsed Persia when Alexander the Great conquered the empire. The incorporation of Persia into the Hellenistic empire brought the land of Darius into a vast and richly diverse empire, an empire that facilitated cultural interchange from Thrace to northwestern India to Trans-Oxiana (west-central Asia). Culture and ideas from this diverse collection of regions flowed into Persia, and Persian culture itself was transmitted throughout the Hellenized parts of the globe.

After Alexander's empire fell apart, one region of Persia, Parthia, began to assert authority. The origins of the Parthians are somewhat obscure, but references to Parthia in the Behistun Inscription (dated to the reign of Darius I, ca. 520 BCE) suggest that the Parthian homeland spanned what is now eastern Iran and parts of Pakistan and Afghanistan. In 139 BCE, Parthia defeated the Seleucid kings who had taken control

At its height, the Parthian empire extended westward up to (and sometimes including) Mesopotamia and east into central Asia. The Parthians played an important role in policing the Silk Roads and seem to have had peaceful diplomatic relations with Han China.

of the region in the wake of Alexander's death. At its height, the Parthian empire extended westward up to (and sometimes including) Mesopotamia and east into central Asia. The Parthians played an important role in policing the Silk Roads and seem to have had peaceful diplomatic relations with Han China. In many ways, the cultural mosaic that was the Parthian empire facilitated the transmission of ideas and goods between regions as geographically distant as Rome and China, and some

eastern Roman cities, such as Palmyra in Syria, were deeply influenced by this relationship. The Parthian relationship with Rome was frequently hostile, however, and eventually the empire disintegrated.

Around 226 CE another empire, based in what is now Iran, arose: the Sassanid dynasty. The Sassanid dynasty controlled a vast empire that stretched from eastern Turkey as far as west-central Asia and Pakistan. Under the Sassanids the arts and sciences flourished until its abrupt fall around 651. In particular, Manichaeism and Judaism prospered in the initially tolerant and cosmopolitan Sassanid empire. Manichaeism was a Gnostic religious tradition, founded by Mani (ca. 216–276 CE), that combined elements of Zoroastrianism, Christianity, and other traditions and spread extensively throughout Asia and parts of the Roman empire. Manichaeism fell out of favor at the Sassanid court, which became more militantly Zoroastrian and eventually began persecuting followers of Mani. In its over 400 years of existence, the Sassanid empire vacillated between policies of tolerance and extreme intolerance to the various groups living within its borders. Outside of its borders, the influence of the Sassanid dynasty was especially felt in the arts and sciences. The art and textiles of the Sassanids were desired and emulated from Egypt to China. After the era ending in 300 CE the Sassanid kings became patrons of philosophy and literature and continued some of the traditions of Greek philosophy.

South Asia

By 1000 BCE, the northern Indus-Ganges region of South Asia could be characterized as the home of an Indo-Aryan civilization. This was a time when there was no centralized authority throughout South Asia; rather, the region was divided into numerous small city-states and other forms of polity. The period from 1800 BCE to about 600 BCE is often referred to as the Vedic Age (since this was the culture in which the Vedic texts were written). It was in this culture that Hinduism was born, and it was in this culture that the Indian caste system (which was eventually dominated by Brahmins) developed. The Brahmins were the highest class in what is called the *varna* system and held authority over priestly and religious matters, although this dominance was initially contested by the Kshatriya, who were the previously dominant aristocratic class.

From 600 BCE on, the authority of the Brahmins was gradually questioned. This questioning manifested itself in numerous new religious traditions. Wandering philosophers, called *shramanas*, questioned the meaning of life and the current social order. Some of these shramanas gained large followings, and schools developed based on their teachings. One of the longest lasting of these traditions surrounds Siddhartha Gautama, the Buddha. The Buddhist tradition seems to have been established around 500 BCE, although there are problems with precisely dating when the Buddha lived. The followers of Siddhartha Gautama believe that he attained enlightenment, and his teachings became the core of Buddhism. (The term “Buddha” means “awakened one” and is a title, not a personal name.) Another important teacher, roughly contemporaneous with the Buddha, was Vardhamana, the Mahavira (Great Man), an important figure in the establishment of Jainism (named after Vardhamana’s title “*jina*,” or “conqueror”). The early stories of the Mahavira are similar to those of Siddhartha, and it is difficult to untangle history and tradition. However, most Jains see the Mahavira as the last teacher in a long line of teachers rather than the founder of this movement, which emphasizes *ahimsa* (total nonviolence toward all living beings) and believes that there are immediate consequences (karma) for individual actions.

The larger political context of these religious changes, especially manifest in Buddhism and Jainism, was one in which numerous small kingdoms had arisen. While only minimal archaeological work has been done on sites dating to this period, current evidence suggests that this was a period of increased urbanization, especially in the Ganges.

Alexander the Great’s armies entered northwestern India in 326 BCE, but this Hellenistic incursion was not long-lived. In the aftermath of the Macedonian king, India was divided into numerous small kingdoms that warred and competed with one another. By 322 BCE one of these kingdoms, led by Chandragupta Maurya, arose and united much of South Asia into a large unified state. This marked the beginning of what scholars call the Mauryan period, which lasted until the collapse of Mauryan authority around 185 BCE. The empire extended over most of the Indian subcontinent (as far as Kalinga along the eastern coast) and north to the Himalayas in the northeast and into Afghanistan in the

northwest. The most noteworthy of these Mauryan kings was Chandra-gupta's grandson, Aśoka (r. ca. 269–232 BCE). Aśoka converted to Buddhism and sent missionaries to Ceylon, Burma, Egypt, Anatolia, and west-central Asia to spread the teachings of the Buddha. Modern historians know much about Aśoka's reign because he set up numerous pillars and rocks throughout his empire inscribed with his royal proclamations that extolled the virtues of the Buddhist Dharma (Law) and prescribed behavior consonant with those teachings.

In 185 BCE, a coup within the Mauryan empire led to its collapse after an extended period in which the size of the empire had shrunk. Northern India divided into numerous small kingdoms. These small kingdoms fell prey to numerous foreign invaders from the north. One of these groups was led by a Greco-Bactrian king named Demetrius, who around 180 BCE conquered southern Afghanistan and Pakistan and established an Indo-Greek kingdom, under which Buddhism thrived.

A succession of foreign powers competed over this northern region. The most successful of these foreign groups was the Kushans (called the Yuezhi by the Chinese), an Indo-European group whose vast territory ranged from Tajikistan and Afghanistan to north-central India and across the Pamirs into east-central Asia. The most famous Kushan leader was Kanishka (r. 127–147 CE) who, like Aśoka, was a follower of the Buddha's teachings, although true to the syncretic ways of the Kushans, he incorporated Mithraic elements into his religion. Kanishka was responsible for convening the famous Fourth Buddhist Council in Kashmir, where the Buddhist canon of sacred sutras, known as the *Tripitaka*, or *Three Baskets*, was established. His extension of the Kushan empire as far east as the Tarim basin probably was a factor in the early transmission of Buddhism into western and northern China. Indeed, the Kushan empire maintained contact with Rome, Persia, and China throughout its existence and was a major intermediary between Europe and Asia. Under the Kushan empire a major revolution in Buddhist art and iconography occurred, associated with Gandhara (a region in southern Afghanistan/northern Pakistan). This new form of Buddhist art fused Greco-Roman-Mediterranean designs and styles with those from India. This Gandharan Buddhist art was brought east to China and beyond, where it fused with East Asian styles and led to the emergence of a new distinctly East Asian art that incorporated significant Greco-Roman and Indian elements.

Beginning around 230 CE, at the same time as the Kushans ruled the north, the Satavahana dynasty ruled the south of India. Under the sponsorship of the Satavahanas, Hinduism spread to Southeast Asia. Buddhism also thrived in this context. Some of the finest Buddhist art was created under the patronage of the Satavahana kings, and great Buddhist stupas were erected throughout the Krishna River valley.

China and East Asia

Around 1027 BCE, the Western Zhou dynasty conquered the Shang dynasty in China and instituted a system of subordinate territorial rulers who were left to their own devices. By 771 BCE the power of the Zhou

had eroded, and the borders were threatened by people to the west. A confederation of rebel vassals and Rong tribespeople overran the Zhou capital, and the king was killed. The Zhou moved their capital east to Luoyang in 770 BCE, never again controlling the territory west of the Wei River, thus beginning what historians call the Eastern Zhou period. Until 256 BCE the Zhou continued to reign in China, if only in name. In practical terms, China had become a vastly decentralized collection of individual polities.

The first half of the Eastern Zhou period is also known as the Spring and Autumn period (722–481 BCE). This name is derived from the *Spring and Autumn Annals*, which chronicles historical events from this time and was supposedly edited by Confucius but was actually edited later. This was the period of Kongfuzi (Kong the Eminent Philosopher), known in the West as Confucius (ca. 552/551–479 BCE). It is impossible to exaggerate the importance of Confucian thought to China, and while none of his own writings survive, The Analects (Lun Yu, which means “ethical dialogues”) preserve his supposed words as assembled by his students after his death. Daoism was likely formulated prior to the age under consideration here, although tradition holds that Laozi, one of the most important Daoist thinkers and the supposed author of the *Daodejing* (*Classic of the Way and Virtue*), the core Daoist text, was a contemporary of Confucius. Along with the intellectual achievements of the age came a number of other important innovations. Iron was first used, and direct taxation systems were introduced. The soybean was introduced to the rest of China from Manchuria and became an important staple of the Chinese diet.

In the latter half of the Eastern Zhou period another great thinker, Mozi (ca. 470–391 BCE), influenced students in China, emphasizing self-reflection over ritual obedience and offering arguments against Confucian values (many of which reemerged in twentieth-century Chinese political discourse). His writings coincide with what is called the Warring States period (traditionally understood as running from 453 to 221 BCE), a name that aptly describes the final stages of the Eastern Zhou. The Mohist school and its system of logic were prominent during the Warring States period but did not survive the suppression of learning that took place after the Qin conquest, referred to as the “burning of books and burying of scholars” (213–206 BCE).

The Warring States period was a time of intense warfare, as conflict and competition between states intensified. In this period of war and conflict intellectual life flourished, and many classics of Chinese philosophy were composed in a political environment characterized by conflict between regional warlords. Mencius, or Menzi (ca. 371–289 BCE), was an important philosopher, concerned especially with good governance. His interpretation of Confucius was extremely influential to later Chinese philosophers. Xun zi (298–238 BCE) developed an elaborate theory of human nature and society that became very important in the later

It is impossible to exaggerate the importance of Confucian thought to China, and while none of his own writings survive, The Analects (Lun Yu, which means “ethical dialogues”) preserve his supposed words as assembled by his students after his death.

Han dynasty. His works were extremely critical of Daoism, Mohism, and competing Confucian views. Sun Tzu (Sunzi) wrote his *Art of War* during the Warring States period, a classic in military theory that applied Daoist philosophy to military strategy. This ancient work has played an important role in warfare well beyond Warring States China. Traditionally, historians have credited the book with providing the First Emperor of Qin with the strategies to end the Warring States period and unify China. The samurai of Japan revered the book after its introduction there in 760 CE. Napoleon is thought to have absorbed its teachings and used some of its principles in his European wars.

By the end of the period, the Qin was the last remaining state, itself ruling China from 221 to 206 BCE. Qin incorporated Legalist principles of statecraft, a doctrine that arose in the Warring States period and is most memorable for its harsh punishments. The Qin dynasty did not last long after the death of its first emperor, Qin Shi Huangdi (r. 221–210), but two of the most memorable monuments of ancient China date to this period. Tradition holds that construction began on the Great Wall under the reign of the First Emperor. In fact, this was not the Great Wall that visitors to China see today (which dates to the later Ming dynasty). Rather, the First Emperor's wall actually consisted of a number of older walls in the north and west that were upgraded and in places connected. The First Emperor's tomb outside present-day Xi'an also holds splendors of the Qin dynasty. This is near where the numerous life-sized terra-cotta soldiers and officials were interred, probably to guard the emperor's tomb. The main chamber of the tomb has yet to be excavated. After the death of the First Emperor, numerous states revolted against the harsh Qin rule. Eventually a commoner named Liu Bang (usually called Han Gaozu or Han Gaodi, the title granted him posthumously) conquered China in 202 BCE and founded the Han dynasty (202 BCE–9 CE; 25–220 CE).

It took until 154 BCE for the Han dynasty to conquer the remaining Chinese kingdoms that had also rebelled against the Qin. Like the Qin and unlike the Zhou, authority was fully vested in the figure of the emperor, but the bureaucracy enacted actual governance. Emperor Han Wudi (141–87 BCE), the Martial Emperor of Han, was one of the most noteworthy rulers and oversaw the expansion of the Han state concomitant with an intellectual florescence and important agricultural innovations (such as the improved plow). Han Wudi extended the boundaries of the empire far into central Asia. He defeated the Xiongnu (a confederation of nomadic tribes in that region) and opened up the Hexi Corridor, an act that ushered in the first Golden Age of the Silk Roads. With this, Han Wudi sent ambassadors as far as west-central Asia and received horses from the Ferghana Valley in present-day eastern Uzbekistan. The historian Sima Qian lived at this time and fell into disfavor with Han Wudi, who sentenced him to execution. Sima Qian had his execution commuted to castration and was thus able to finish writing his history.

From 9 to 23 CE, the Wang family wrested control of China from the Liu family and attempted to reorganize China along the decentralized lines of the Zhou dynasty. These reforms proved to be undesirable, and

the Liu family regained authority in 25 CE, thus beginning the Later Han dynasty, which remained in power until 220. Also called the Eastern Han (since the capital was moved from present-day Xi'an to Luoyang in the east), the Later Han was initially quite successful. This was a period of tremendous achievements in history writing, philosophy and statecraft, poetry, and the fine arts. However, when the fourth emperor came to power as a child, systemic weaknesses became more apparent as various consort families battled among themselves for control of the Han state.

The first real attack against Han authority came from a sect known as the Yellow Turbans (because of the kerchiefs they wore). The Yellow Turbans rebelled in 184, and while they did not succeed, this revolt led to power being redistributed among military leaders supported by great families throughout China. In 220 one of these military leaders, Cao Cao, gained power in the north. Two other powers arose in the south and southwest, and it was from these three kingdoms that the Period of the Three Kingdoms (220–280 CE) received its name. These three states warred for 60 years until Jin managed to reunite the land in 280. This unification was not long lasting, and in 316 Chinese central authority once again collapsed.

Alongside the political turmoil of the latter stages of the Han dynasty was the spread of Mahayana Buddhism into the northern and western regions of China. The spread of this form of Buddhism into China was made possible by the translation of Buddhist writings into Chinese. A Buddhist monk, Lokaksema (b. ca. 147), is credited with this achievement. Lokaksema was of Yuezhi ethnicity and traveled to the Han court via the Silk Roads. He was not the only central-Asian Buddhist who brought these teachings to China; throughout the last few hundred years of the period, the Silk Roads facilitated the movement of Buddhist missionaries into China, establishing the foundation for the spread of Mahayana Buddhism throughout East Asia.

Japan

In Japan, the Jomon culture, which had begun around 11,000 BCE, continued on until about 300 BCE. This culture, whose name derives from its distinctive rope-pattern pottery, developed numerous innovations in fishing technology in its final years. The Jomon was gradually replaced by the Yayoi culture, which ran from 300 BCE to 250 CE. There is no marked break between the two cultures; the major distinctions lie in styles of pottery made and the introduction of wet-field rice cultivation, probably from China. The introduction of rice agriculture led to larger changes in social structures, and by the end of the Yayoi culture, Jomon elements are no longer prominent. The end of the Yayoi period and the beginning of the Tomb period is also not marked by any fundamental break. Around 250 CE, there is evidence of increasing social stratification. The name “Tomb period” is based on the prominent appearance of elaborate tombs in large tumuli (earthen mounds). The Tomb period lasted until 552 CE, when Buddhism was becoming widely accepted in Japan.

Korea

In Korea, the agricultural economy continued on as it had since before the beginning of this age. As populations grew, so did the social complexity of the region. Sometime between the seventh and fourth centuries BCE (the exact dates are debated by historians, and mythological dates suggest that it was founded during 3000–2000 BCE), the small cities of Korea banded together into a federation called Gojoseon. In the first century BCE the kingdom of Gojoseon fell apart, and although the exact causes are debated by scholars, it is apparent that numerous regional powers sprang up in the aftermath. Most prominent were the three polities that would come to dominate Korea in the following centuries: Koguryo (Goguryeo) in the north, Paekche (Baekje) in the south-central region, and Shilla (Silla) in the southeast. Known as the Three Kingdoms period, this tripartite division of Korea began in 57 BCE and lasted until Shilla conquered Koguryo in 668 CE.

Europe and Western Central Asia

Around the periphery of Greek and Roman civilization in Europe and western Asia, barbarian groups thrived from 1000 BCE to 300 CE. The term “barbarian” was a relatively pejorative term coined by the Greeks (and adopted by the Romans) to refer to those people who did not speak Greek or Latin. While this term has been understood as problematic since its earliest uses, it is still frequently used to refer to the non-Greeks and non-Romans who lived in Europe until the Middle Ages. During this period, the Romans referred to the Celtic groups on both sides of the Alps as Gauls, whom they distinguished from the Germans who lived beyond the Rhine and Danube and spoke Teutonic languages.

Although in modern times Celtic culture is associated with Ireland, Scotland, Wales, Cornwall, and Brittany (in France), Iron Age Celtic culture was much more widely spread across Europe and into Southwest Asia.

These barbarian groups were actually quite diverse. Some were nomadic or semi-nomadic. Others lived in small villages. Most of these people were organized into small political units (usually tribal-based), although there may have been some larger intertribal organizations. Our knowledge of these different groups comes from two primary sources: Greek and Roman accounts (which are intrinsically biased) and archaeological evidence (which is un-

even throughout Europe). Despite these problematic types of evidence, much is known about these barbarian groups from 1000 BCE to 300 CE.

Perhaps most well known are the Celtic tribes, who are first identifiable in this period but developed out of earlier Bronze Age groups. Although in modern times Celtic culture is associated with Ireland, Scotland, Wales, Cornwall, and Brittany (in France), Iron Age Celtic culture was much more widely spread across Europe and into Southwest Asia. The origins of Celtic culture are unclear, but most archaeologists associate the Iron Age Hallstatt culture (1200–500 BCE) and central European La Tène culture (600–100 BCE) with later Celtic populations.

Apart from Celtic culture, numerous other groups inhabited Europe past the borders of Greek and Roman civilization. In eastern Europe, the largest known non-Celtic group was the Thracians, who were concentrated in the Balkan Peninsula. Greek sources tell us quite a bit about one of these Thracian groups, the Dacians, who controlled territory around the Carpathian basin.

Horse-based nomadic and seminomadic cultures were the norm in western Asia from 1000 BCE to 300 CE. The best known of these groups are the Scythians, who roamed the Pontic steppe of eastern Europe/western Asia (that area around the Black Sea that includes much of present-day Ukraine and Russia) throughout this period. The Scythians lived on the outskirts of Greco-Roman and Persian/Parthian civilization, and they may have had contact with the ancient Chinese. Probably speaking an Iranian language, this horse-based society left massive burial mounds (called kurgans) to honor their dead leaders. Archaeologists have discovered volumes of elaborate metalwork in these kurgans, attesting to the highly developed artistic skills of the ancient Scythians.

Kurgans of the Scythian type can be found from the Black Sea to Mongolia, and Scythian culture shared many similarities to the people of central Asia. The nomadic groups of central Asia played important roles as intermediaries between the culture regions of China, India, the Near East, and Europe. The Xiongnu, for example, were a nomadic confederation that lived in the steppe regions to the northwest of China and traded extensively with the Chinese. Conflicts with them encouraged the Qin emperor to build a wall system across northern China, an early predecessor of the later Ming dynasty's Great Wall of China. The Yuezhi, another nomadic group, are well attested in Chinese sources (Sima Qian writes about them, for example), who inhabited east-central Asia and had extensive dealings with the Chinese and likely spoke an Indo-European language. The best evidence for Indo-European languages in central Asia is associated with Tocharian society of the Tarim basin. It is not clear how the Tocharians related to the Yuezhi, although many scholars believe that they were one and the same. The Tocharians lived along the Silk Roads, and much of their wealth must have stemmed from their control of these routes, where they acted as middlemen or charged taxes/tolls on caravans. Central Asia was not only inhabited by nomadic groups. Settled cultures that resided in the oasis towns and cities along the outskirts of the Taklamakan Desert engaged in agricultural and metallurgy and also lived off of the profits of Silk Roads trade. In many ways the settled communities lived in tandem with the nomadic cultures, trading agricultural goods for the animal-based products of a pastoralist economy. The relationship was not always friendly; often the nomadic groups would extort the settlers just as they extorted long-distance traders.

North America

By 1000 BCE, lifeways in North America varied tremendously, much depending on the environmental conditions in each region. Many of these patterns of subsistence continued on much as they had prior to

1000 BCE. Major changes, however, did occur in the American Southwest, the Eastern Woodlands, and the Arctic.

California was home to diverse cultural traditions from 1000 BCE to 300 CE. Many of these continued traditions very similar to those from earlier periods. Most of these groups were hunter-gatherers, subsisting on the rich resources available in the region. In the Great basin, traditions remained similarly stable; numerous lakeside villages suggest that these people exploited a wide variety of wild game, fish, and plant life. On the Great Plains, this was roughly the period known as the Late Plains Archaic (typically dated from 1000 BCE to 500 CE). Life on the plains remained relatively similar to earlier periods. The significant change associated with this period is a change in projectile point technology. Most important is what scholars refer to as the Pelican Lake point, found first in Alberta and Saskatchewan, that improved hunting (especially bison hunting).

There is a significant degree of cultural continuity among the people of the American Southwest prior to 1000 BCE and continuing well past 300 CE. However, throughout this period numerous local variations, especially in technology, created a variety of unique cultural groups. One of the most noteworthy changes in Southwest culture at this time was the gradual adoption of maize agriculture, which coincided with an extended drought in the region.

The Eastern Woodlands of North America saw drastic changes from 1000 BCE to 300 CE. From about 500 BCE on, elaborate mound burials were erected from the Appalachians to the Mississippi Valley and north to Wisconsin. The most elaborate were those in the Ohio Valley, associated with the Adena ritual tradition. This tradition seems to have been a series of ritual practices shared by diverse groups throughout the Eastern Woodlands. The burial mounds and sacred earthen circles of this tradition are still easy to spot to this day. One of the best-understood groups that developed out of the Adena Tradition are the Hopewell People centered in the Ohio Valley, who first appeared around 200 BCE and disappeared around 400 CE. The Hopewell continued the Adena traditions of elaborate burial mounds and large earthen enclosures. They also became the center of a large trade network (called the Hopewell Interaction Sphere by archaeologists). This network extended a considerable distance, all the way to Florida. From about 1 CE on, there is strong evidence of greater social stratification in Hopewell society, most evident in the increasing variation in wealth in the burial mounds.

From 1000 BCE to 300 CE, three distinct cultural traditions emerged in the Arctic: the Norton, the Thule, and the Dorset. While much is still poorly understood about the early stages of these cultures' history, it is apparent that this was a seminal period for them. The Norton and the Thule thrived in the western Arctic, whereas the Dorset developed in the eastern Arctic. It is apparent that from around 700 BCE the Arctic started to become colder and colder, thus forcing these groups to develop new survival practices.

The Norton people are most associated with Alaska and especially the shores of the Bering Strait. It is likely that they maintained close contact with people living in Siberia, although the extent of these inter-

actions is not yet well understood. As temperatures got colder from 700 BCE on, the Norton moved farther and farther away from Siberia. The origins of the Norton people are not entirely clear, but since they used tools reminiscent of the earlier Arctic Small Tool tradition (2500 BCE–1000 BCE), there was likely some connection. The Norton lived in permanent settlements along the coast and exploited both caribou and maritime resources. The Thule tradition developed out of the Norton tradition (ca. 700 BCE); this new group concentrated on marine mammal hunting for its subsistence, developing kayaks and harpoon technology.

The Dorset people, located in the eastern Arctic, appear around 550 BCE, seeming to develop out of the earlier Pre-Dorset tradition. The Dorset are often taken as the ancestors of the modern Inuit, and Inuit legend describes these people as giants and legendary hunters. Archaeological evidence suggests that they lived in semi-subterranean homes and relied primarily on seals for food. Archaeology and Inuit legend both agree that these early ancestors lacked dog sleds and sophisticated hunting technology. Harpoons allowed them to eke out a living based primarily on hunting, and some of their artwork still survives to the present.

The Dorset are often taken as the ancestors of the modern Inuit, and Inuit legend describes these people as giants and legendary hunters. Archaeological evidence for the Dorset suggests that they lived in semi-subterranean homes and relied primarily on seals for food.

Mesoamerica

The period from 1000 BCE to 300 CE marks a time of tremendous change in Mesoamerica (Mexico and Central America) in which many of the most important trends for the next 1,000 years were established. This was the period when the Olmecs, the first complex civilization in the region, reached their apogee and then disappeared (merged into other cultures in the region). It is the period in which the first stirrings of Maya culture can be safely identified. And it is during this period that the urban center of Teotihuacan emerges as a regional powerhouse.

Starting around 1200 BCE, the Olmec civilization emerged in the tropical lowlands of south-central Mexico. The Olmecs were long thought to be the “mother civilization” of the later Mesoamerican societies, although this theory is coming under increasing attack as more contemporaneous but non-Olmec sites are explored. Regardless, the Olmecs were an important early complex civilization who developed an elaborate writing and iconographic system and were highly urbanized. Many of their cultural developments (such as human sacrifice, bloodletting, ball games, a complex calendar, mathematics, and mythology) were adopted and adapted by the later Mesoamerican civilizations. Other traits did not continue and remain specific to the Olmec culture, most notably the gigantic stone heads and altars. The first center seems to have been the site of San Lorenzo, which was abandoned around 900 BCE. Following this, the site of La Venta rose to prominence and

remained the largest and most elaborate Olmec city until the decline of the civilization around 400 BCE, when the population of the region declined significantly. It is unclear what exactly brought Olmec civilization to an end, but a number of diverse city-states developed in the region immediately afterward.

From about 400/300 BCE to 250 CE (the Late Preclassic period), Maya civilization began to develop the traits that would typify the Classic Maya (usually understood to date from 250 to 925 CE). Here are the origins of the complex civilization that consisted of independent city-states that interacted through warfare and trading alliances and dominated much of Mexico. The elaborate architecture, advanced writing system, and mythological traditions seem to have their origins in this Preclassic period, although writing is not common until very late. While Maya culture certainly originated much earlier (as early as 1800 BCE), this is the period in which those cultural, artistic, and technological features most associated with the Maya are first apparent. While the Maya certainly shared many characteristics with the Olmec and likely adapted much of Olmec culture, scholars are divided about whether the Maya should be considered the descendants of the Olmec or if they developed out of a variety of ancient traditions.

Around 200 BCE the first buildings were constructed at Teotihuacan, which would grow to become one of the largest and most powerful cities in Mesoamerica. Located in the Teotihuacan Valley in Mexico, the site could not support a large population until the development of sophisticated irrigation technologies made large-scale farming feasible. Once the subsistence base was established, the city grew tremendously. Its highly organized grid plan was relatively unique in Mesoamerica, but its sprawling pyramid and temple complexes may have been the basis for later ritual centers. The population was highly stratified, with extremes in wealth and status apparent in the size and opulence of the structures. The city exerted a powerful influence throughout Mesoamerica, linking much of the region through the exchange of prestige and agricultural goods and through the exaction of tribute upon less-powerful centers. By 300 CE Teotihuacan had a population of over 100,000 people and was nearly 8 square miles (over 20 square kilometers) in size, one of the largest cities in the world.

South America

At the same time as these movements toward greater social complexity and urbanization occurred in Mesoamerica, parts of South America underwent similar changes. In the central Andes a number of complex cultures flourished: the Chavín, the Moche, and the Nazca. The Chavín culture appeared first, in the north-central Andes, developing out of a variety of earlier traditions. Notable for its distinctive art, the major center of the Chavín was the site of Chavín de Huántar, which was most substantially occupied from 900 to 200 BCE. Around 1 CE and lasting until about 600 CE, the Moche culture appeared on the northern coast of Peru. Skilled metallurgists and ceramicists, the Moche also built elab-

orate pyramid complexes supported by large urban populations. Concurrently, the Nazca (or Nasca) culture blossomed in southern Peru, creating their own unique pottery styles. They dotted the landscape with large lines, shapes, and figures by removing the stones from the desert, revealing the lighter-colored topsoil underneath. These Nazca lines, as they are popularly known, are still evident in the Peruvian landscape today, although their original use is debated by archaeologists.

A number of complex societies emerged in the southern Andes as well. From about 1300 to 100 BCE, the Chiripa culture built large stone architecture. This was followed by the Pucara culture (100 BCE to 100 CE). However, the largest group to arise in the southern Andes was the Tiwanaku culture, located near Lake Titicaca. The Tiwanaku first emerged around 400 BCE and lasted until about 1000 CE. However, it is not until about 400 CE that the Tiwanaku reached its maximum extent.

Oceania

The human settlement of Oceania from Southeast Asia continued throughout this age. The migration of the people of the Lapita Complex had extended Southeast Asian culture as far as New Caledonia by around 1000 BCE. The further establishment of human communities on the Pacific Islands continued elsewhere in the Pacific. The islands of Melanesia were settled by horticulturists associated with the Lapita Complex only starting at around 1100 BCE, despite the fact that New Guinea had had a human presence for centuries longer. Starting around 400 BCE, ceramics manufactured in Papua, New Guinea, began to be extensively traded, and by about 1 CE extensive trade networks had been established with the islands of Southeast Asia.

Micronesia likewise saw an intensification of human settlement after 1000 BCE despite the fact that beachside middens (garbage heaps) and tools dating to earlier times have been recovered by archaeologists on some of the islands. Many of the Micronesian sites established during this age were coastal; structures were suspended on stilts built directly on top of reefs. The site of Nan Madol (Pohnpei), which seems to have been first occupied about 2,000 years ago, was one such site, which eventually grew into a series of 93 artificial islands linked by canals. The Polynesian Triangle (bordered by Hawaii, Easter Island, and New Zealand) was the location of the most easterly Lapita movement, and distinctive Polynesian culture can be said to have emerged by 800 BCE. These early Polynesians had come via Fiji, spoke an Austronesian language with origins in Malayasia, and were primarily horticulturalists who brought pigs and dogs with them. By about 500 BCE, the distinctively Lapita material culture had given way, and Polynesian culture began to diversify into separate traditions.

In Australia, artistic and material culture forms that had emerged prior to the period here considered (1000 BCE to 300 CE) continued in their use and elaboration. The so-called X-ray style of rock art (the earliest examples probably date to around 2000 BCE) was elaborated on throughout this age and continues to develop in the present. This is a

distinct style of rock art in which humans and animals are drawn in silhouette. Their internal organs and/or skeletons are depicted within the line and thus the images look like X-rays. The rock paintings at Ubirr (in the Kakadu National Park) may be the best known, and while painting in the rock shelters there may have begun as early as 40,000 years ago, the majority of the paintings that are still visible today date from about 2,000 years ago.

The Stirrings of Late Antiquity

Many scholars of the Mediterranean regions and Europe see the third century CE as a transitional phase between Classical Antiquity and the Medieval Age. Scholars who see this as a meaningful periodization describe this transitional time as “Late Antiquity,” although they rarely agree on finite beginning and end points. Whether or not one accepts this designation of a distinct transitional phase of history, many elements of culture worldwide from the latter half of the third century onward point to greater continuity with what comes after than what came before.

Politically, much of the unity brought by the rise of major world empires began to fragment. Up until the third century, much of Eurasia was connected by four major empires centered in the Roman Mediterranean, Persia/Mesopotamia, central Asia/India, and China, but as the interconnectedness brought by these empires collapsed, the connections and lifeways among the peoples of Afro-Eurasia were transformed. From about 235 to 284, the Roman empire experienced what is often called the “Crisis of the Third Century,” in which the empire almost collapsed due to civil war, outside invasion, and internal pressures such as plague and hyperinflation. Around 258–260, the Roman empire split into three somewhat competing states, and although it was reunified under Diocletian, his division of the empire into east and west set the stage for the later more permanent division of the Roman world into East and West. In India by about 220 CE the Satavahana empire disintegrated, leaving in its place several dynasties ruling over a largely decentralized India that was not centralized again until the rise of the Gupta empire (around 320). China also experienced a period of disunity beginning in 220 and extending for the next three and a half centuries. Although briefly reunified by the Western Jin dynasty (between 280 and 304), much of China’s north was lost to nomadic peoples, precluding anything even approaching a unified imperial state. In contrast to Rome, India, and China, the mid-third century was a period of growing centralized control in Persia under the Sassanian dynasty. After a disastrous defeat by the Romans in 298, the Sassanians ceded control of some of their western provinces but established a peace with Rome that allowed them to develop stability in Persia.

The transitional features of Late Antique Europe were in many ways influenced by the nature of contacts with the rest of Eurasia from the mid-third century onward. The most overt examples of this Eurasian influence were the barbarian invasions (which began around 259) of

the Roman empire that, in various waves, altered the demographic makeup of Europe. Related to this, the later medieval tendency toward the construction of defensive walls around cities arguably began with the construction of the Aurelian wall (271–275) around Rome to protect the city from barbarian invaders. Similarly, the plague that ravaged Roman society around 265 may have been transmitted along the Silk Roads, prefiguring the periodic plagues that would devastate the Mediterranean and regions beyond in the sixth and fourteenth centuries.

The transformations in religion that began during the third century (but fully took root in the fourth century) are some of the most dramatic breaks with what had come before. By the end of this period, the “ancient” religions of Egypt, Mesopotamia, Greece, and Rome had begun to vanish. Christianity became a mainstream religious movement within the Roman empire, so much so that in 337 the Roman emperor Constantine was baptized as a Christian (on his deathbed). Concomitant with its growing population of worshippers, the distinction between Christian laity and clergy became more distinct. The growth of Christian monasticism in third-century Egypt was one manifestation of the separation of sacred and secular, and although initially monasticism developed outside of the authority of the Church, it became a fundamental component of the medieval Church. As Peter Brown has argued, holy people replaced holy sites as centers of refuge, help, and solace. The beginnings of the spread of European Christianity beyond Rome can be found in the missionary movements of the mid-third century. For example, tradition holds that Saint Denis was martyred by pagan priests in Paris in 250, who were alarmed at his successful conversion of the local population. Whether or not this story can be taken as historical, the conversion of pagan populations (often from the top down) became a hallmark of Late Antiquity. Missionary tendencies in other parts of the world had developed earlier. The beginning of the spread of Mahayana Buddhism into northern and northwestern China and the rise of Daoism as a religion in China in the third century dramatically altered the landscape of belief in that region, setting the stage for a Buddhism that was centered in East Asia and a Daoism that competed with Buddhism and Confucianism for influence in China.

In Mesoamerica, however, scholars take the “Classical Age” to have just begun in the mid-third century. Archaeologists employ the periodization “Classic” for the cultural transformations that began around 250 CE, just as “Classical Antiquity” was drawing to a close in the Roman world. As the Classic period began in Mesoamerica, Teotihuacan rose to become the largest city of the Americas (and one of the largest cities in the world at its time). The Maya cities of the southern lowlands (such as Tikal, Palenque, and Copan) entered their era of greatest florescence.

Thus, both the ends and beginnings of Classical Traditions can be seen in the mid-third century. The end of ancient history began in the mid-third century, and over the next 700 years many of these Late Antique trends continued, with the spread of Buddhism and Christianity, the rise of India and China as cultural innovators, and the growth of densely populated Maya, Andean, and Amazonian civilizations.

Environment and Population

Life in the Arctic changed dramatically between 1000 BCE and 300 CE when the first villages appear along the coast. These villages are part of what archaeologists call the Norton tradition, which first appears along the coasts of Alaska (adjacent to the Bering and Chukchi seas) coincident with a massive warming period. The considerable variation in material culture from village to village along the coast suggests that these communities remained relatively isolated from one another. What these villages did share was an increased reliance on marine resources, especially marine mammals, for subsistence. Advanced harpoons, well suited for hunting seals and even larger prey such as walruses and whales, have been recovered from these sites. Most of these villages would have been permanent settlements, although some campsites may have been used by hunters only in certain seasons. The wealth of marine resources allowed the people of northern Alaska to remain in one location throughout the region's radically different seasons. Even after 700 BCE, when temperatures became dramatically colder, the wealth of marine resources allowed the people of the Norton tradition to thrive until about 800 CE.

Throughout the period 1000 BCE to 300 CE, extreme environments, such as the Alaskan coast, came to be more fully exploited by human populations. Arid areas, such as the Transjordan, became more heavily settled. The domestication of the camel allowed human populations to begin crossing the deserts of Asia and Africa. The spread of agricultural techniques from China to Southeast Asia and Japan allowed greater security in subsistence practice in those regions. Maize agriculture had become an essential component of Maya life. The Pueblo people of the American Southwest also began planting maize in this period, one of the brief times when that region of the world was suitable for this kind of agricultural production.

This was a period of massive population movements and demographic shifts. Many scholars believe that this was a period in which Bantu-speaking peoples spread throughout much of Africa. The steppes of Eurasia were heavily traveled by a variety of groups, including the so-called barbarian tribes that would come to cause problems for the Romans after 300 CE. Throughout Western Europe, Celtic and Germanic groups moved around the fringes of the Roman empire. In parts of Mesoamerica that had been previously settled, larger cities began to form, including the sprawling city of Teotihuacan (the largest city ever in the pre-Columbian Americas) that would come to dominate the region near modern-day Mexico City until its decline in the sixth and seventh centuries CE.

With these population movements came some of the first systematic attempts to map the world. The Greek philosopher Hecataeus of Miletus (ca. 550–ca. 476 BCE) is often described as the first geographer and is credited with writing two major works on geography, although these survive only in fragmentary form. In China, Pei Xiu (224–271 CE) introduced numerous advances into the practice of cartography, and although his critical studies of cartography and mathematics are preserved in some forms, none of his maps are extant.

In China, Pei Xiu (224–271 CE) introduced numerous advances into the practice of cartography, and although his critical studies of cartography and mathematics are preserved in some forms, none of his maps are extant. By far the most influential geographer in this period was Ptolemy, who lived in Roman Egypt from 83 to 161 CE. Best known now for his geocentric view of the universe (that the earth is the center of the universe), he produced numerous other influential works. His *Geographia* summarized much of what was known about and beyond the Roman empire in his time. Pliny the Elder (d. 79 CE) could also be classified as a geographer as well as a natural scientist. His work *Natural History* purports to cover all fields of knowledge and includes extensive discussion on geography and the natural world. In many ways, *Natural History* is a precursor of today's encyclopedias.

The Romans, whose empire spanned major portions of Europe, Southwest Asia, and North Africa from the period of the Roman republic to well beyond 300 CE, ruled over numerous diverse environmental regions. The Italian peninsula, with its Mediterranean climate, had significantly different environmental characteristics from Rome's arid Levantine holdings in the eastern Mediterranean and its highland and boreal North European holdings. Despite the immense varieties in the Roman landscape, Roman cities and infrastructure were relatively standardized. Aqueducts allowed the Romans to bring vast amounts of water into their cities and freed them of the need to build their cities directly by a water source. Roman building technology allowed them to create structures that could withstand the harsh winters of the north and the hot summers of the desert. Heating and cooling technology meant that these buildings could be comfortable no matter where they were located. Of course, this Roman environmental mastery was not without its costs; ancient deforestation is apparent (through the analysis of ancient pollen) in many areas where the Romans once held power. Human costs were also apparent; the utilization of vast amounts of slave labor had profound demographic consequences.

Roman technology, however, could not prevent major environmental catastrophes. The rich volcanic soil located around modern-day Naples is present because of the still-active Mount Vesuvius, which erupted in 79 CE and destroyed the Roman cities of Pompeii and Herculaneum. Mount Etna, located on the island of Sicily, had previously erupted in 122 BCE, causing much devastation on that Roman island. It was not just the Romans who suffered through a volcanic eruption during this period. Around 50 BCE, the town of Cuicuilco was covered by a lava flow, forcing the inhabitants to flee the region.

Earthquakes were equally destructive. The Phrygian city of Laodicea (located in Anatolia) was destroyed by an earthquake around 65 CE. An earthquake in Syria in 89 CE may have killed upwards of 100,000 people. In 226 BCE, one of the Seven Wonders of the World, the Colossus of Rhodes, was toppled by an earthquake. The fallen colossus remained a tourist spectacle for the next 800 years.

Agriculture, the dominant subsistence practice for a vast proportion of the world's population, was also susceptible to environmental problems. Drought was one of the major concerns. In China, droughts beginning in about 18 CE led to varying degrees of famine. In 25 CE the flooding of the Yellow River further weakened the already fragile Chinese agricultural economy. In 92 CE locusts exacerbated the problems even further. Locusts were a problem for the Romans as well. In 125 CE locust plagues in North Africa led to grain shortages in Rome (and a concomitant rise in prices).

■ Introduction: Climate Change and Natural Disasters

Archaeologists thrive on past natural disasters. Whether it be an earthquake that toppled ancient buildings or a volcanic eruption that covered a city in ash, these unexpected disasters ironically preserve ancient life in a way that no other depositional processes do. When people prepare for change or change willingly, they will take their valuables away; usually they do not leave their homes in the condition in which they lived in them. That is why the eruption of Vesuvius in 79 CE and the concomitant destruction of the Roman cities of Pompeii and Herculaneum have been so important for archaeologists. Herculaneum was a small seaside resort located near Neapolis (modern Naples), and Pompeii was a larger center, inhabited since Greek times. When Pompeii was covered by volcanic ash from Vesuvius in 79, it had not fully recovered from an earthquake that had damaged much of the city in 62 CE. The eruption of Vesuvius itself was well documented by Pliny the Younger. Pumice fell for almost 18 hours following the eruption of Vesuvius. Following this, poisonous gasses and lava surged periodically, and slow lava flows emptied down the south and southeast of Vesuvius.

Similarly devastating was the eruption of the volcano Xitle in the Valley of Mexico, whose

lava flows covered the ancient site of Cuicuilco. The ash falls and lava flows were so dense that archaeologists have to use jackhammers to reach the ancient artifacts. The exact dates of Xitle's eruption are debated, but it must have been sometime between 400 BCE and 400 CE. Earthquakes in this period were similarly disruptive. Earthquakes damaged the sites of Laodicea, Rhodes, and other locales in this period. Climate change on a less rapid scale was just as devastating. The gradual desertification of North Africa in the last 1,000 years before the Common Era has dramatically altered the settlement patterns of that region. The following entries detail some of the examples of climate change and natural disasters that are well attested for this period.

The Destruction of Pompeii

The major Roman city of Pompeii was destroyed by a volcanic eruption originating from Mount Vesuvius on August 24, 79 CE. The explosion covered Pompeii and the neighboring city of Herculaneum under layers of volcanic ash and pumice, preserving the cities for posterity and

➤ DEATH IN POMPEII—THE ERUPTION OF MOUNT VESUVIUS

On the morning of August 24, 79 CE, the eruption of Mount Vesuvius, which lasted for nearly an entire day, caused widespread panic in Pompeii. As some people streamed to leave the city amid a hail of ash and pumice, many others felt that it would be best to stay behind under shelter. However, as the pyroclastic flow (torrent of pumice, hot ash, rock, and volcanic gas) rushed toward the cities of Herculaneum and then Pompeii, hundreds met their end from the intense heat emitted by the surge. Those who survived the hail of pumice were asphyxiated by the noxious gases emitted by the flow. As a result of the layers of ash and pumice that covered the corpses amid multiple panicked deaths, archaeologists were able to find preserved remains of people whose body language strongly suggests the apprehension and terror at the moment of their death.

—*Abraham O. Mendoza*

thus allowing contemporary archaeologists and historians to delve into the quotidian existence of ancient Rome. Excavations in the past century have given archaeologists a glimpse into Roman society in the first century CE and have thus contributed significantly to the development of both historical and anthropological scholarship. Notwithstanding the historical value of the ruins of Pompeii, the eruption of Mount Vesuvius itself stands as a significant natural disaster that was regarded as a catastrophe by contemporaries such as Pliny the Younger.

Pompeii and Herculaneum were part of a series of towns surrounding the base of Mount Vesuvius, adjoined by an agriculturally prosperous region near the city of Naples in Campania. Pliny the Younger (61–112 CE), who observed the eruption of Mount Vesuvius from Misenum across the Bay of Naples, provided the first account of the disaster (though he wrote it 25 years after the event). Death by asphyxiation from the poisonous gases or the mass of ash unleashed by the eruption immediately killed many of the city's residents, many of whom were unable to evacuate in time from the environs of the city or from their own residences. Pliny the

Younger's uncle, Pliny the Elder, as Admiral of the Imperial fleet, died trying to assist in evacuation efforts in the midst of the disaster. Due to Pliny the Younger's documentation as well as that of other historians, the destruction of Pompeii was preserved as part of the Roman historical record.

The actual excavations of Pompeii and Herculaneum did not occur until well into the fourteenth century CE. A local aristocrat contracted the construction of water channels, which necessitated digging in the vicinity of the ruins of Pompeii in 1549. While laborers found antique artifacts and inscriptions in the midst of their work, they were met with indifference. More extensive excavations did not occur until 1709, when a local resident digging for a well discovered marble from the ruins. The land was bought to be used as marble quarry for the construction of a villa for an Austrian military official, which led to the excavation of the theater of Herculaneum. However, the Spanish ousted the Austrians from this region of Italy, and it became part of the Spanish dominions. As a result, Spanish military engineer Giocchino de Alcubierre supervised the excavations of the site, followed by Swiss engineer Karl Weber. By 1738, the site was identified as the ruins of Herculaneum, and by 1748 excavations had begun on the adjacent site of Pompeii.

During this period, significant finds were made amid the excavations such as bronze sculptures, libraries of papyri rolls (such as the Villa of Papyri), and other examples of Roman architecture, art, and technology. Preserved houses, public buildings, and theaters were found, which allowed archaeologists to view well-preserved manifestations of Roman architecture and daily life. Art, in the form of sculpture, inscriptions, paintings, and mosaics, also gave scholars a glimpse into the culture and aesthetic appreciation of the ancient Romans. Many of these findings were intact, as the layers of ashes protected these artifacts from the wear and tear of the centuries since the eruption. With the identification of Pompeii in 1763, local efforts were made at converting the site into a tourist destination.

In the nineteenth century further excavations were made, albeit with a more scientific approach and a will to preserve the sites for his-

torical and archaeological reasons. Systematic excavation of the sites was conducted under the aegis of Italian archaeologist Giuseppe Fiorelli from 1863 to 1875 (commissioned during the process of Italian unification by King Victor Emmanuel). The sites were excavated by sector, and the findings and process were documented meticulously by Fiorelli, with greater efforts made at preserving the sites and allowing findings to remain in location rather than being extracted. These practices have continued into the present, as Pompeii remains a major tourist destination (it was declared a UNESCO site in 1997). Despite the catastrophic nature of the disaster and the mass death of the inhabitants of the region, Pompeii remains an important archaeological find for posterity, as it offers the modern world a snapshot of life in ancient Rome.

The Destruction of Cuicuilco

Cuicuilco is a little known but important ruin situated within the southern urban footprint of Mexico City. It is arguably the oldest city of central Mexico, the precursor for a series of great cities—Teotihuacan, Tenochtitlan, and Mexico City—located in the same valley, each of which have been the largest American city of its era. Cuicuilco, which may have had 20,000 inhabitants at its peak in about 100 BCE, exhibited political specialization, organized religion, ceremonial architecture, complex burial practices, long-distance trade, and calendrical astronomy. The city was composed of temple mounds, ceremonial plazas, pools for irrigation, and extensive residential housing. Compared to other ancient American ruins, we know relatively little about Cuicuilco's origins or history. We do know the cause of its demise, however, which is often the most difficult question of archaeology. A

Cuicuilco's main temple mound, Mexico City.
(Shawn W. Miller)

massive eruption of the nearby Xitle volcano covered the entire city in as much as 33 feet (10 meters) of lava, leaving only the very tops of Cuicuilco's largest pyramids exposed. Molten rock reached to Lake Texcoco, blanketing 30.8 square miles (80 square kilometers) of the valley floor. The cataclysm helped preserve many artifacts from the period, but the tomb of solid rock has made Cuicuilco's extent difficult to visualize and has made archaeological investigation, which requires jackhammers and heavy equipment, expensive.

Cuicuilco's presence beneath its lava vault was not discovered until the early 1920s. Manuel Gamio, after studying at Mexico City's School of Mines and then completing a PhD with Franz Boas in anthropology at Columbia University, recognized San Cuicuilco, what had long been thought a hill, as a temple mound protruding from the lava field's surface. After a few minor excavations that proved the mound to be man-made, Gamio invited Byron Cummings from the University of Arizona to join his investigations. Cummings arrived with funding from the National Geographic Society that permitted the purchase of machinery to remove the encumbering rock layer. Beginning in April 1922, workers unearthed the 89-foot (27-meter) pyramid that was unusual for its circular form and, hence, not a true pyramid but a truncated cone built in tiers from its 394-foot (120-meter) diameter base. It had a stone (rather than earth) core and was dressed in rough volcanic rock. The Xitle

volcano had probably been partially active for much of Cuicuilco's existence, which placed the fire god Huehuetēotl at the top of the local pantheon. The temple mound's conical form may have been in imitation of Xitle's near-perfect volcanic cone. Two ramps, on the east and west, accessed the mound's sacred platform from which the smoke of sacrifice and incense, like Xitle's exhalations, would have risen to the heavens. As excavations tunneled into the top of the mound, Cummings revealed a number of unusual altars, some oval in shape. He estimated that the pyramid, in typical Mesoamerican fashion, had been rebuilt upon itself some five times.

Gamio identified the ceramic and burial objects found under the lava as related to a period and people previously known as the Culture of the Sierra but that he now denominated as the *Cultura Subpedregalense*, that is, the culture found beneath the Pedregal lava field. Pottery

styles proved links to the Olmec culture. Gamio's ceramic series dated Cuicuilco in the Middle and Late Formative periods, roughly 700 BCE to 150 CE. Cummings, however, believed the city to be more than 8,000 years old based on estimates of the lava's age and of deposition rates of the ash beneath the lava. His claim would have made Cuicuilco one of the world's oldest cities and its pyramid the world's first. His claim would remain controversial for half a century. Unfortunately, Cummings published little of his work on Cuicuilco because the briefcase in which he kept all his papers was stolen from a local train station.

In the 1950s, new studies provided a better sense of Cuicuilco's extent: a total of 17 pyramids were identified. And in the late 1960s, a number of new excavations were commenced in a rush to salvage artifacts that were to be built over by facilities for the 1968 Olympic Games.

Dozens of residential foundations were uncovered, both circular and rectangular, most of them with finished stucco floors. Radiocarbon dating finally made a reliable challenge to Cummings's initial estimate. After many trials testing charred vegetation just below the lava layer, scholars believe that the eruption could not have occurred before 50 CE or any later than about the year 300, corroborating Gamio's ceramic evidence that placed Cuicuilco's origins about 600–400 BCE. The city was abandoned at the time of the eruption, and the presence of household images of Huehuateotl, Cuicuilco's fire god, in Teotihuacan suggests that some of Cuicuilco's inhabitants migrated north to live beyond the reach of the valley's southern volcanoes. Cuicuilco's ruins remained a place of pilgrimage for centuries after the disaster.

The most recent major discovery at Cuicuilco is a 13-foot (4-meter) stele, or obelisk, buried vertically beneath the footing of the main pyramid. Covered with a variety of decorations, some associated with Huehuateotl, it is believed to have served an astronomical purpose and is the oldest stele discovered in the Americas.

Because of its location within an ever-expanding city and despite its importance, Cuicuilco's archaeological zone remains under constant threat. Much of the complex has been

built over, including by many edifices on the National University campus. More recently, in the late 1990s, despite laws that protect Mexico's cultural patrimony, a large shopping mall, the Plaza Cuicuilco, and an office complex have superimposed themselves on portions of the ruins, which upset many Mexicans. From one perspective, new buildings form just one more layer in the archaeological stratigraphy. But much has been lost that might help us understand the origins of civilization in the Americas. What remains of Cuicuilco's original site is a fenced island of desert plants clinging to the lava substrate, surrounded and threatened on all sides by multilane highways and commercial and residential development.

■ Introduction: Changes in Food Production and Water Management

Food and water are fundamental human needs, and any changes in practices associated with acquiring either have a significant impact on human populations. For archaeologists, identifying differences in subsistence strategies (strategies for acquiring food and water) are indicative of significant cultural changes as well. For example, around 1000 BCE the people of the Arctic developed hunting technologies that allowed them to take advantage of the wealth of marine life located on the Alaskan coast. The stable migration patterns of sea mammals and the abundance of food (and subsidiary products) led to the establishment of permanent settlements.

From the period 1000 BCE to 300 CE, one of the most notable changes through Asia and Africa is the spread of rice cultivation, which required significant alterations in the landscape and day-to-day work life of the people who adopted rice into their diet. Agriculture also spread throughout the American Southwest at this time, allowing year-round settlements in what had previously been marginal regions.

This period is also noteworthy in that food- and water-management practices developed that allowed people to make use of land that was previously inhospitable or underutilized. It is in this time that grape and olive production spreads

from the eastern Mediterranean to the west (the ancestors of the Italian, French, and German vineyards that provide such a large percentage of today's world wine and olive supplies). Water systems throughout the Americas allowed more stable permanent settlements as people learned to control their water resources. Simple (but effective) hydraulic systems were put into place in the desert fringes of the Near East and central Asia, allowing land that was previously uninhabitable to sustain small centers and caravan stopping points.

—Kevin M. McGeough

The Beginning of Banana and Rice Cultivation in Africa

The development of cultivation in sub-Saharan Africa is still poorly known, but recent discoveries have shed new light on this subject. Apart from evidence of domestic pearl millet in the early second millennium BCE and probably cowpea slightly later, domesticated plants are not attested in sub-Saharan Africa until the first millennium BCE or the early centuries CE. Archaeological finds outside Africa, however, do not suggest a complete picture: crops of African origin, sorghum (bicolor type), pearl millet, cowpea, and hyacinth bean have been reliably identified from parts of South Asia in contexts of the late third or earlier second millennium BCE. This must indicate that these, and probably other crops, were already under cultivation in Africa by this date and probably considerably earlier.

Settlements with ground-stone tools, grindstones, and pottery are known from the rain forests of central Africa. Most date from the first millennium BCE or early first millennium CE, but some may have had pottery by 3000 BCE or even earlier. The people occupying these settlements probably lived by hunting and gathering but also planted oil palms and encouraged useful forest species such as bush-candle trees. In later times bananas (plantains) were the main staple of rain forest horticulture; it has been suggested that yams provided the staple until the

introduction of bananas, although yams do not grow well in the rain forest, which lacks the dry season they require.

The earliest literary reference to bananas in Africa dates to the sixth century CE. Until recently, bananas and other Southeast Asian crops were thought to have been first introduced when Madagascar was settled by people from Island Southeast Asia sometime in the mid-first millennium CE. These people probably also settled on the East African coast or at least were in contact with communities there.

However, some scholars had begun to suggest, on linguistic grounds, that bananas had been introduced to the east coast of Africa much earlier, before 1000 BCE; the diversity of plantain varieties in the African rain forest also indicates an early introduction. Recent discoveries now provide support for this theory. Excavations at Nkang in Cameroon yielded phytoliths (microscopic silica plant remains) from the domestic banana, *Musa* sp., dated to 840–350 BCE. (There are as yet no criteria established to distinguish between phytoliths of the different banana varieties; however, it is assumed that the Nkang phytoliths are from plantains.) This is currently the only direct evidence for early horticulture in the African rain forest. Contacts between groups across the continent presumably carried bananas to the forest region, where they, rather than yams, may have been the first crops cultivated by the region's inhabitants. Anthropologists Edmond De Langhe and Pierre de Maret suggest that the introduction of the plantain may have been responsible for the first-millennium increase in rain forest villages.

The domestic banana has a long and complex genetic history, not yet fully known, involving the development and hybridization of several varieties, principally *Musa balbisiana* (B phenotypes), whose distribution today extends from southwestern China through Burma into India, and *M. acuminata* (A phenotypes), which has a more restricted distribution, within Southeast Asia. Hybrids between these species developed at an early date, as did diploid and triploid varieties. Genetic research indicates that *M. acuminata* var *banksii*, which was cultivated in

New Guinea perhaps as early as 7000 BCE, contributed the AA genome in the plantain, an AAB hybrid. Where the plantain developed is not yet established; both New Guinea and eastern Island Southeast Asia have been suggested. The plantain spread into western areas including southern India, which became a secondary center of development. Phytoliths of domestic banana were recently discovered at a Harappan site, Kot Diji, in the third millennium BCE. It is therefore possible that it was from South Asia that bananas were introduced to Africa, perhaps through the same contacts that took African crops to South Asia.

In contrast to the rain forest, farmers in the highlands of East Africa, and particularly the Great Lakes region, today cultivate a sweet banana, the triploid (AAA) *M. acuminata*, known as the East African cooking banana. Its introduction may date from the Southeast Asian colonization of Madagascar. While domestic animals were kept in East Africa from the third millennium BCE by groups who also hunted, fished, and exploited local plants, cultivation is currently not evidenced until the mid-first millennium CE.

However, a startling discovery was made in 2005: banana phytoliths, apparently much earlier, in sediment cores from Munsa, a papyrus swamp in the Ugandan highland. The paleoenvironmental evidence from the cores reflects a forested environment without agriculture in the immediate vicinity until relatively recently (second millennium CE), but banana phytoliths appear at irregular intervals throughout the sequence, from the basal deposits dated before 3500–3100 BCE and others before 2000 BCE as well as from much more recent dates. The deposits in the swamp include organic materials that eroded from sediments in the surrounding area, some possibly considerably earlier than the swamp deposits. If the dates reflect the age of this material, this would provide a possible explanation for the puzzling date of this find. If, however, the phytoliths genuinely date from before 3500 BC, there must have been contact between Africa and South or Southeast Asia far earlier than is currently accepted, an exciting and challenging prospect.

➤ JENNÉ-JENO

The location of Jenné-jeno close to the confluence of the Bani River with the Niger gave its inhabitants access to rich supplies of fish, abundant land for grazing during the dry season, and extensive floodplain suitable for rice cultivation during the inundation, when domestic stock were probably moved to upland areas. During the first period of the settlement's occupation, from around 250 BCE to 99 CE, its inhabitants fished, raised domestic cattle and caprines, and exploited local wild plants and animals but also cultivated rice, pearl millet, and sorghum. Wild plants remained important throughout the settlement's history. The town reached its apogee in the period 300–800 CE, probably growing to more than 98 acres (40 hectares). Local agricultural productivity, combined with its situation at the interface between river-borne trade to the north and trade with the highlands to the southeast, enabled Jenné-jeno to grow into a major town with well-developed craft industries, trading fish and rice in exchange for copper, iron, gold, and stone as well as fruit and probably salt. Even in the first period there were stone beads and iron at the site, brought in through interregional trade. Jenné-jeno's agricultural produce helped maintain the trading towns farther north at the Niger bend such as Timbuktu, which were the contact points for trans-Saharan trade. After 800 CE the town began to decline, and by the fifteenth century it had been abandoned in favor of a settlement 1.8 miles (3 kilometers) to its northwest.

—Jane R. McIntosh

Bananas and plantains became important staples in parts of Central and East Africa. Farther north in the western regions of West Africa, this role was taken by African rice (*Oryza glaberrima*). The harvesting of wild rice is known by 1200 BCE at Gajiganna in Nigeria. Rice cultivation is still believed to have been a relatively late development, probably in the Inland Niger Delta. Jenné-jeno, the principal settlement of this region, was established around 250 BCE; crops present throughout the occupation included rice, grown on the floodplain during the inundation, and sorghum and millet, grown as

décru crops, planted on moist soils left by receding floodwaters and requiring neither rain nor irrigation. Recent excavations have pushed back the date of rice cultivation in the region to around 800–700 BCE, a period for when a large quantity of domesticated rice was recovered at Dia, on the Diaka River, 62 miles (100 kilometers) northwest of Jenné-jeno.

It is likely that the first cultivation used floating rice, a variety that grows long stalks as the flood waters rise and that is often harvested from a canoe; cultivation may subsequently have spread to regions where nonfloating varieties could be grown in shallower water and finally to upland areas where varieties suited to dry cultivation were developed. Rice provided a staple crop that in some areas probably eclipsed other earlier cereals, but the seasonal differences in crop requirements meant that in many cases both rice and other cereals could be raised. This was the case, for example, at Jenné-jeno.

The Spread of Agricultural Development South of the Yellow River in China

Beginning from the ninth century BCE, the state of Chu emerged in the central Yangtze River basin, south of the Yellow River. When the Yellow River basin became one of the five areas in the world where agriculture developed the earliest, the vast land of the Yangtze River was primarily covered by forest and sparsely settled by different tribal peoples. Since the founding of Chu, the ongoing migrations from the North were greatly accelerated; as improved technology spread, agriculture in the southern land developed rapidly. Also, the Chu state made many attempts to promote economy to finance its continuous warfare, which further stimulated the agricultural development southward in China.

Exactly how the state of Chu started up remains a question. The legend claims that its ruling house, the Xiong family, descended from a clan that originated in the Yellow River region. After gaining a foothold in the central Yangtze River basin, the Xiong family gained the recognition of the reigning dynasty of Zhou in the ninth century BCE and thus began its ruling lineage. While the story may reflect the southward migration of the people from the more densely populated north, the reality may be more complicated. The Chinese records referred to the tribal peoples originally settled in the Yangtze River basin as Bai Pu and Bai Man, or "various tribes of Pu and Man." Most of these tribal peoples spoke languages other than the Chinese in the North; they grew rice but relied on an earlier farming technique, that of burning and slashing. The ruling family of Chu might well indeed come from the North, but as a newcomer and likely smaller in numbers, the Chu must have had to work with these various local peoples. The result was more likely a hybrid culture that grew out of the continuous marriage between the northern and the southern cultures. In fact, two centuries after the founding of Chu, the more Chinese states in the North refused to accept the Chu as an equal on the ground that it was of Man, a degrading term for the non-Chinese peoples. The Chu ruler did not defend himself, though; instead, he was

proud of being a Man, saying that in that way he would not observe the rules and norms of the North.

The continuous fusion between the northern migrants who came with the Chu ruling lineage and the local tribal peoples resulted in the rapid spread of agricultural development southward in China. The migrants from the Yellow River basin brought with them to the South more advanced technologies. Among these technologies were iron metallurgy and irrigation. Irrigation, in particular, had been developed in the North for many centuries and was instrumental in the success there. On the other hand, the South enjoyed some natural advantages: more rainfall, warmer temperatures, and better access to rivers and lakes. The technological advantage of the North when combined with the natural advantage of the South resulted in the fast growth of thriving agriculture in the Yangtze River basin. The power and influence of Chu grew most significantly during the reign of King Zhuang (613–591 BCE) and the growth owed largely to the building of many state-sponsored irrigation projects in its territory. Of these, the largest one was in present-day Gushi, south of Henan province, that allowed the Chu to more effectively harness the water resources of the Huai River. Since its founding the Chu expanded in all directions, with the most gains in the South. Unlike elsewhere, the aborigines across the land south of the Chu were tribal peoples; the absence of well-organized resistance was key to the Chu's great success there. By the fifth century, the Chu influence had reached much of the middle and lower Yangtze River basin as well as present-day Yunnan province in the Southwest. As the Chu continued to expand, farming technology spread farther, and agriculture developed consequently.

The agricultural development in the Yangtze River basin owed much to the state policy of the Chu. In addition to building irrigation projects, the Chu rulers also adopted other policies to promote the opening of the South. Because the acquisition of land in the South outpaced the movement of people, the Chu statesman and one of the most well-known strategists Wu Qi formulated a reform, forcibly moving wealthier fami-

➤ GENERAL WU QI, THE CHU REFORMER

Wu Qi was one of the best military strategists in ancient China, usually paired with the world-famous Sun Zi; together they are usually referred to as Sun-Wu. Another important part of Wu's life, one that is less known, is that he was also a political statesman and a reformer. A native from the state of Wei in the north, Wu spent most of his youth in search of a career but did not get his best chance until he moved to Chu in 390 BCE. He was first made a general responsible for border defense, and after his unusual vision and talent were well proven, he became the prime minister of Chu in charge of political reform. His reform consisted of a series of policies to strengthen the military and to enrich the country, and the centerpiece of it was to weaken the aristocratic power by relocating the wealthy families to the frontiers. Wu's reform brought about agricultural development and greatly enhanced the king's power but also alienated the aristocracy. After King Dao of Chu died in 381 BCE, Wu was killed by the aristocrats in a coup d'état. When the reform came to an abrupt end, the fortune of Chu also started to go downhill.

—Yi Li

lies within the kingdom and resettling them in the frontiers. While such a reform policy might have encountered opposition from these wealthier families, the government-led migration brought immediate effects. Among the warring states, the Chu had long built a reputation as a state that had all its granaries filled, so its people did not have to worry about famine. To encourage his soldiers to fight harder, the Chu king often rewarded them with large amounts of grain. For example, Wu Zixu, an enemy of Chu for the great damage he did to the state, was wanted at 50,000 *shi* (one *shi* is about 100 pounds) of grain. The agricultural development in the South gained for the Chu necessary and valuable resources in its bid for dominance in China.

Roman Aqueducts

While the Romans did not invent the concept or basic design of aqueducts, they certainly perfected their efficient application in supplying reliable water to the cities throughout their empire.

In Roman aqueducts, the principle of gravity flow carried water through an enclosed conduit (*specus*) that usually ran on the surface or underground, from the source in neighboring hills to a distribution tank (*castellum*) in the city, located at the highest attainable point to allow widespread distribution. Settling tanks (*piscinae*) were usually built both at the source and along the course to settle out impurities and to aerate the water. Within the city, pipes (*fistulae*) of either terra-cotta or lead were tapped off the *castellum*, run below the stone pavement of

streets, and fed into fountain houses (*nymphaea*) and other points of use.

The requirements for a suitable source of water were stringent: pure water, year-round flow, sufficient elevation to allow a constant gradient into the city, and yet enough distance from human and animal habitation to be uncontaminated. Vitruvius gives detailed recommendations on how to find sources of groundwater and determine its purity: an examination of the topography, the nature of the soil, surface vegetation, the presence of moisture, and even water diviners for the former; and, for purity, a study of the appearance of the water, suspended particles, and even the health of those who live nearby. Other sources, including the medical writer Hippocrates and Pliny the Elder, rank rainwater as the most pure, but acknowledge that underground springs are most commonly used for feeding aqueducts, in part because of their reliability. Despite this, at least two of the aqueducts that supplied Rome took their water directly from the Anio River northeast of the city.

➤ FRONTINUS AND THE AQUEDUCTS OF ROME

When Frontinus became curator of Rome's water supply in 97 CE, nine aqueducts had been built to feed the city, beginning with the relatively short *aqua Appia* in 312 BCE and eventually totaling 272 miles (438 kilometers) in length. The first two were largely subterranean; thereafter arcades were used to carry the channels across the plain that lay between Rome and the hills to the east. To save on expenses, several separate channels could be superimposed one on another, making use of the same arcade, or channels from different sources were joined together and their waters mingled.

These conduits fed elevated cisterns, from which the water was distributed through clay or lead pipes first to innumerable fountain houses (*nymphaea*) that supplied water for drinking and cooking to most of the inhabitants; public baths (the smaller *balnea* and the immense *thermae*) contributed to a relatively high standard of personal and public hygiene; and the presence throughout the city of public latrines and drains helped prevent regular outbreaks of disease. Rome

in 100 CE boasted a water management system unequalled in Europe until the nineteenth century, with a bureau of the civil service in charge of maintenance and of ensuring equitable distribution.

The maintenance of such an essential and complex system, and the need to supervise the fair distribution of the water to baths and industries as well as to individuals, required an equally complex bureaucracy. We are fortunate to have Frontinus as our guide to this system, a curator of the water supply who was so determined to encourage his successors to maintain his rigorous standards of maintenance and enforcement that he composed a two-volume handbook, which still survives, containing detailed descriptions of the hydraulic and engineering elements of the system, of the laws that governed the distribution of the water, and of the creative ways that Romans surreptitiously tapped into the public system to bring a private supply to their homes.

—John W. Humphrey

Wisely, the water was first channeled into a settling tank, where it would be held motionless to allow the coarsest of sediment to fall to the bottom. From there it was led into the conduit for its journey to the city. If the water was not clear and potable when it entered the city (and several aqueducts brought muddy and even foul-tasting water into Rome), the inhabitants had a variety of techniques for purifying it: by boiling, by filtering it through porous amphorae, sand, charcoal, and wool, by desalination (evaporation followed by condensation), and—most commonly—by mixing it with wine to camouflage the taste and, at least in theory, to counteract impurities.

To those unfamiliar with the details of Roman water conduction, the term “aqueduct” conjures up images of stately arches marching across the plain of Latium toward the walls of Rome. While this is not imaginary, it is unusual: both finances and security made such elegant structures relatively uncommon, though they are even now the most visible remnants of the system. In fact, most channels were by preference built along the surface of the ground or in a shallow trench, and covered with slabs to prevent evaporation. To avoid long detours around hills, the channel was occasionally accommodated in a subterranean tunnel, and only when traversing a deep gorge or a flat plain was the gradient maintained by elevating the conduit on arcades.

Because many of the water sources were heavy with calcium carbonate, the floor and walls of the conduit would often become encrusted with lime, a deposit that archaeologists call by its German name, *sinter*. By building settling tanks, particularly at the source, the Roman engineers tried to precipitate out most of the limestone, but regular removal of the accumulated (and remarkably hard) sinter was necessary to maintain the proper flow of the aqueduct. Very occasionally and (so far as the evidence suggests) only in a few regions of the empire—southern France and Asia Minor particularly—did the Romans avoid the necessity of arcades by connecting the gravity-flow conduit to a kind of “inverted siphon” based on the principle that water in a closed system finds its own level.

Regular access holes from the surface allowed regular maintenance and cleaning of the channel, at least annually to remove the accumu-

lated sinter and other deposits. Repairs were to be done speedily, because the regular flow could be shut off only at the source, thus temporarily depriving thousands of city folk of their water supply.

The Introduction of Rice into Southeast Asia

Although wild rice was exploited from early times in Southeast Asia, domesticated rice and agriculture were apparently introduced rather than developed locally. Strong similarities between the distinctive pottery of Yunnan in southern China and that found, along with agricultural tools, domestic animals, and sometimes rice remains, in settlements in mainland Southeast Asia, such as Non Nok Tha in Thailand, Samrong Sen in Cambodia, and Phung Nguyen in Vietnam, suggest that rice farmers spread south from China along the Red (Hong) River, Mekong, and other major rivers around 2500–2300 BCE. By 2000 BCE probable farming settlements are known as far south as the coastal plains of Malaysia, such as at Jenderam Hilir in Selangor.

Settlements were established along streams and tributaries in these river valleys. Stone or wooden hoes and digging sticks were used to clear the land of weeds. Often no ground preparation was required before sowing, though domestic cattle might be used to puddle the soil. Rice was probably sown by broadcast on seasonally inundated land, the plants growing in the moisture left as the floodwaters receded. The rice was harvested with slate or shell knives. At first, the areas settled by farmers were limited. For example, in the Red River valley, early farming settlements were mainly upriver of its confluence with the Black River. From around 1500 BCE, agriculture became much more widespread, mainly in inland areas. Rice, along with

PHILIPPINE AGRICULTURAL TERRACES

Remarkable terraced paddyfields on the slopes of Luzon's Cordillera Mountains were probably constructed around 2,000 years ago. Those of Ifugao Province are now a UNESCO World Heritage site. The terraces follow the hillsides' contours and were artificially built up. A drystone wall forms the outer edge of each terrace, behind which gravel was packed, topped by a thick layer of hard-packed soil and finally a layer of topsoil, creating a terraced field that holds water for growing paddy rice. Using a complex system of earthen channels, wooden and bamboo pipes, sometimes with dams and sluices, water from springs and rainfall on the rain forests of the higher slopes is supplied to the staircases of paddyfields, finally collecting in the rivers below. Conservation and sustainable use of the forest are an integral and vital part of the system's maintenance and viability. The slow and managed descent of the water protects against flash floods and erosion. Modern neglect of terrace maintenance in some areas is having serious consequences. Similar hillside terracing for rice cultivation exists elsewhere, including Nepal, China, Vietnam, Thailand, and Indonesia, but the Luzon terraces on their precipitous slopes are the most spectacular.

—Jane R. McIntosh

domestic animals and often fish, provided considerable prosperity, reflected in elite burials furnished with valuables made of imported and local materials including copper and bronze, which were now worked.

Some scholars argue that this spread of farming can be correlated with the region's colonization by speakers of Austro-Asiatic languages. These are spoken today in parts of mainland Southeast Asia and pockets in India. An early Austro-Asiatic language may have been spoken in southern China. Formerly it appeared that rice was domesticated once, in China, and spread from there through Southeast Asia into India; correlating this with the spread of Austro-Asiatic speakers then seemed plausible. Now, however, genetic evidence has shown that there are two distinct varieties of rice, separately domesticated in China (*Oryza sativa japonica*, by around

4500 BCE) and India (*Oryza sativa indica*, probably during the third millennium BCE). Moreover, it now seems likely that India's Austro-Asiatic (Munda) languages were widely spoken at an early date, making it possible that the Austro-Asiatic language family originated in India. Whatever the truth of this, it is now necessary to decouple the spread of rice cultivation and the spread of Austro-Asiatic languages, which should be investigated separately.

Both *japonica* and *indica* rice are now grown in Southeast Asia, which lies within the range of the wild ancestors of both. At some stage another variety, tropical *japonica* rice (formerly known as *Oryza sativa javanica*), developed in Southeast Asia. This resembles *indica* but actually developed from *japonica*. The problems of confidently distinguishing among the three varieties, using the limited rice remains recovered from early Southeast Asian sites, make the delineation of their history in the region exceptionally difficult.

Although colonists introduced rice agriculture, the onward spread of farming through Southeast Asia is likely to have involved a mosaic of mechanisms: further movement by the colonists' descendants, acculturation of local hunter-gatherers by their farming neighbors, and the circulation of agricultural produce and technology among hunter-gatherers themselves through the wide-ranging exchange networks. This is exemplified at the coastal settlement of Khok Phanom Di in Thailand, occupied during 2000–1500 BCE, where foragers exploiting local wild resources used rice probably obtained from an inland farming settlement. However, for a short period when the sea level fell, creating a freshwater environment, the villagers, while still using local wild resources, also grew their own rice, using granite hoes and shell harvesting knives, which appear in this period and disappear after it.

The spread of agriculture through Island Southeast Asia has also been linked with the spread of a language family, Austronesian, in this case more persuasively. By 2500 BCE farming was established in Taiwan, home of the Proto-Austronesian language. The spread of agricultural settlements through much of Island Southeast

Asia and into the Pacific and the regional cultural groupings that developed are consistent with the evolution and distribution of the Austronesian language groupings across this region.

Rice cultivation was established in the northern Philippines (where it is known at Pamittan on Luzon around 2000 BCE). Rice grains or rice impressions in pottery have been found at a few sites farther south, dated to 2500–1900 BCE, including Gua Sireh and Niah in Sarawak, Kimanis Cave in East Kalimantan, and Ulu Leang Cave in Sulawesi. However, conditions within the equatorial belt are not ideal for growing rice. It is possible that cereal farmers moving into central Island Southeast Asia abandoned rice in favor of tree crops and tubers (as certainly happened in the eastern part of the region). This could explain why there is no evidence of rice cultivation in islands farther south (such as Java and Bali) until later, when it may have been introduced from the mainland or by traders from India. Sembiran in Bali, dated to 200 BCE–300 CE, has rice phytoliths, implying local rice cultivation; much material here relates to Indian contacts. Pollen evidence from Java and Sumatra indicating permanent forest clearance around the end of the first millennium BCE probably reflects the beginning of agriculture on these islands.

Farming settlement was largely confined to coastal regions and river valleys in the Southeast Asian islands, where rice was probably grown using slash-and-burn (shifting) agriculture, which is still common here. In this, a cleared plot is cultivated for a few years and then left fallow for a far longer period to recover its fertility through secondary forest growth.

Rice cultivation intensified during the later first millennium BCE. Agricultural occupation spread from the river valleys to higher river terraces and uplands. Chinese involvement in northern Vietnam from the second century BCE probably gave this region access to new agricultural ideas. Bronze tools interpreted as plowshares appear at this time; the buffalo-drawn plow made it possible to prepare much larger areas of land for cultivation. Historical records show that wet rice agriculture, practiced in China for millennia, began in northern Vietnam by 200 BCE. Productive but labor-intensive, this involved

creating permanently flooded paddyfields using bunds to retain rainwater. Rice seedlings were raised in nursery beds and transplanted into the inundated fields. Fertility in paddy fields is maintained by the oxygen in the water and by the presence of blue-green algae, which fix nitrogen. Wet rice cultivation was probably not practiced in other regions of Southeast Asia until the early first millennium CE. Such intensive cultivation allows double-cropping or even continuous cropping; it was generally confined to areas with high population densities, while less intensive systems continued elsewhere.

Ironworking became widespread on the mainland around 500 BCE; at a similar time, knowledge of copper/bronze and iron metallurgy was spreading in Island Southeast Asia. Iron tools facilitated forest clearance and ground preparation for agriculture.

Construction of large moated settlements in northeastern Thailand, Cambodia, and Vietnam probably began around 400 BCE; they later became more widespread. These dominated good agricultural land and other natural resources, housed substantial populations, and were centers of industrial production. Moats and bunds retained water from natural streams; some settlements also had reservoirs. In the early centuries CE more substantial water-control systems were constructed in some areas, including irrigation channels, tanks (reservoirs) and river weirs and sluices at Beikthano Myu in Burma, and networks of canals in the lower Mekong plain.

Development of Peruvian Water Systems along the Coast and in the Mountains

In the dry coastlands of western South America as well as in the steep terrain of the Andes mountains, water has been a significant concern of human populations, a limiting factor in population growth and the sustainability of agriculture, and a possible factor in the development of centralized political and social structures. Rivers may flow only intermittently in dry coastal valleys, providing no surface water to directly sustain plant and animal life. In the mountainous areas, runoff can be rapid due to steep slopes, and even pasture land may need additional water in order to support domesticated herds of animals. With water such a precious commodity, it is not surprising that many early cultures focused on water as a source of economic well-being as well as an object of veneration. Unique and ingenious water-control systems developed independently at the highland center of Chavín de Huántar, in the Nazca drainage on the southern coast, and in the Moche region along the northern coast. In all of these places, water became a source of both economic and social power.

Chavín de Huántar is a famed Early Horizon (800–200 BCE) ceremonial center at the conflu-

ence of two rivers in the Callejon de Huaylas. Chavín grew from a small village before 460 BCE into an important and imposing religious pilgrimage center by 390 BCE. Surface irrigation of the valley floor augmented the agricultural capacity of the area to the point of sustaining a village population of 2,000–3,000 people. The field irrigation system was effective but unremarkable. It was the monumental architecture at Chavín that made it a center of religious attention, however.

Far more remarkable than the irrigation of the valley is the complicated water-control system associated with the Chavín's ceremonial architecture. The architectural complex called the Castillo was constructed of cut stone interlaid with clay as opposed to adobe bricks of other contemporaneous monuments throughout the Andes. Additionally, drains ran throughout the structure and under its plazas to redirect water away from the architecture and into the Mosna River. More importantly, however, the drains could be flushed with water drawn from the irrigation system, creating spectacular sound effects during important ceremonies. That the sound of rushing water may have had ceremonial significance testifies to its immense social and spiritual importance.

Nazca culture (100 BCE–1000 CE) straddled several different water regimes encompassing the Ica Valley to the north and the northern and southern sections of the Rio Grande de Nazca drainage. While there is evidence that this area may have been more humid in the past, for ancient Nazca people water control was important. Nazca people from the beginning probably made use of seeps, springs, and water from seasonal flooding. These sources were important enough, especially seasonal water flowing down from the mountains, that many of the triangular and rectangular geoglyphs may have been created as part of a system of worship honoring mountain deities as the givers of water and fertility.

People began creating the most sophisticated of Nazca irrigation systems during the Middle Nazca period (Nazca 5, 450–550 CE). Colloquially referred to as *pukios*, the filtration galleries of the Middle and Late Nazca (Nazca 6, 7, and 8, 550–1000 CE) tapped into the subsur-

Remains of a Nazca irrigation system. The system appears to have consisted of a number of subterranean aqueducts and canals to siphon off water from natural sources. (Jarno Gonzalez Zarraonandia)

face water table in the southern Nazca drainage and made it accessible for human use. Reservoirs and surface canals were fed by stone-lined tunnels dug horizontally into the water table. *Ojos*, or smaller round openings along the subterranean portions of the galleries, allowed light and air to reach people digging and maintaining the filtration system below in addition to providing access to the water itself. Development of this water-control system allowed Nazca people to expand their settlements significantly in the southern Nazca drainage.

Moche people and their predecessors along Peru's northern coast also developed extensive systems of irrigation canals in order to reclaim land and make it arable. Canals were dug with digging sticks, but only some were lined. The size and length of canals grew over time from a longest length of 4.3 miles (7.0 kilometers) in the earliest phases to up to 17.3 miles (28.0 kilometers) in the later phases of construction. Irrigation of the Moche Valley began as early as the Guañape phase (1800–400 BCE) when small canals maintained and used by social groups of 900 people or less expanded the cultivated area of the lower and middle valley to approximately 10,131 acres (4,100 hectares). Irrigation grew substantially during the Salinar phase (400–1 BCE) and again in the Galinazo (1–200 CE), Early Moche (200–400 CE), and Middle Moche (400–800 CE), reaching more than 30,888 acres (12,500 hectares) of irrigated land supporting tens of thousands of people. Even more land became arable during the Late Moche (800–900 CE) and Early Chimú (900–1000 CE) when people built an intervalley canal of more than 43 miles (70 kilometers) directing water from the Casma Valley to the Moche Valley.

Even with the irrigation canals in place, water would have been in short supply in the Moche Valley, and periodic water shortages would have occurred, maybe as frequently as every three years or so by the end of the Moche period. Control over agricultural production and food surpluses through control of water provided a significant basis for social, political, and economic integration in the Moche Valley during both the Guañape and Moche phases. At least some scholars, however, now reject the idea that bureaucratic and managerial control

➤ A TRADITION OF WORSHIPPING WATER

Water is essential everywhere, but in the Andes water had spiritual as well as economic significance. Some of the earliest ceremonial architecture along the coast faced the mountains, the source of water running through dry valley floors. The Chavín prized rare seashells of strombus and spondylus as symbols of fertility and included images of fishlike and shrimplike creatures in its iconography. The Nazca imagined a killer whale as a powerful supernatural being and may have used zigzag and spiral designs on pottery and in geoglyphs as part of a water cult. The Moche depicted elaborate fishing scenes and culture hero-deities that battled fierce fishlike and crablike monsters.

Arctic Hunting Strategies

For people who have never lived there (and for some who have), the word "Arctic" conjures up a landscape that is almost incredibly forbidding. However, the Inuit, over the course of thousands of years, learned to live successfully in that cold, rugged country. Inuit (plural of Inuk) means "People" in the native language. In recent years, and especially in Canada and Greenland, it has replaced Eskimo, an Algonquian word meaning

THE KAYAK

Although kayaks varied somewhat from place to place, they were basically one-man, closed-deck hunting canoes. They were made of a wooden frame lashed with sinew and covered with sewn seal or caribou skin. Men propelled them with double-bladed paddles and used them mainly for hunting. Skin-covered umiaks were larger, open boats, used either for whale hunting or simply for transportation, depending on the region. In the latter case they were rowed or paddled by women. Sleds, pulled by dogs and/or people, were used for winter travel. These were built of a wood frame lashed together with rawhide. The wood, hide, or bone runners were often covered with moss and then ice to ensure a smooth ride.

—Barry M. Pritzker

“eaters of raw meat” and one that many Inuit find offensive. The Unangan, or Aleut, are also generally considered to be Arctic, rather than Subarctic, residents.

The Arctic is a remarkable region in several ways. It stretches 5,000 miles (over 8,000 kilometers) from Asia (Siberia) to Greenland and 1,800 miles (2,900 kilometers) from southeast Labrador to the Queen Elizabeth Islands. It encompasses well over 2,000 miles (3,200 kilometers) of the Alaska coast and is generally considered to include the 1,000-mile-long (1,600 kilometer) Aleutian Island chain. Another way to think of the vastness of the Arctic region is that it is roughly 12,000 miles (20,000 kilometers) from the eastern Aleutian Islands and along the coast of northern Alaska and Canada to Greenland. Four modern nations claim Arctic lands: Canada, Denmark, Russia, and the United States.

Arctic winters are long, dark, and extremely cold, but are not as cold right along the Pacific Ocean and adjacent waters. Although the interior may be colder in winter, fierce winds blow relentlessly along the coast. The flat tundra is covered with ice and snow in winter, but owing to poor drainage and the presence of permafrost it becomes boggy in summer, a perfect environment for mosquitoes, black flies, and other such insects. Although there are few or no trees in most of the Arctic, there are, during the brief summer,

dwarf flowers, mosses, and lichens. As little as four inches (101 millimeters) of precipitation may fall in a year, except for Labrador and especially southwest Alaska. It is fortunate that ocean ice tends to lose its salinity after a year or so; otherwise finding fresh water would have been a serious problem for many Arctic residents.

A hunting tradition known as Arctic Small Tool (Denbigh Flint complex) arose around the Bering Sea from the Paleo-Arctic peoples of the rest of Alaska and northern Canada around 5,000 years ago. After about 1,000 years it had diffused throughout much of Alaska and Canada. These people made small flint blades, skin-covered boats, bows and arrows, needles, semiexcavated houses, and stone lamps. In the east, this complex was further refined into the somewhat more sea-oriented Dorset Tradition by about 1000 BCE. Dorset people also adapted well to snow and ice, possibly originating the snow house.

Again beginning in the Bering Sea area, the Norton culture materialized about 2,000 years ago. It in turn gave way to the Thule culture, which gradually overtook all other cultural traditions save the Aleutian by about the twelfth century. Thule people had dogs and sleds, umiaks and kayaks, the bow and arrow, and the harpoon thrower (atlatl), and they hunted whales. Through increased specialization and adaptation to local environments, this culture led directly to those found by non-natives.

Hunting sea mammals—ringed and bearded seals, walrus, narwhal, and whales—was the main occupation of most Inuit men. Hunting walrus was considered inordinately dangerous, owing to the animals’ size and aggressive nature. (Polar bears presented the same problem and were taken, if at all, mainly for their hides.) Most men hunted seals from ice floes in winter. This was an extremely demanding task. Seals must come up for air, so men waited with their dogs and various equipment (see discussion of key technologies that applied to hunting) at breathing holes. In order to catch one seal, a man might have to guard a hole for hours, motionless in the dark and bitter cold. Breathing-hole sealing was done communally, so that a number of holes could be covered at once.

Whaling was a special occupation practiced mainly in northwest Alaska. The whaling umi-

aks were led by a captain and chief harpooner. Once the great animal was fatigued by the initial thrust and from the drags, it would slow down enough for other men to spear it to death. The whale was then either towed to shore or left to drift back. In the case of seals and whales, the kill was divided according to very precise and respected formulas.

Depending on the season, a number of subsistence activities took place. Men stalked seals on the ice or harpooned them on open water from kayaks. Birds such as ptarmigan, ducks, and geese were taken, as were their eggs. In some areas, people gathered berries. Fishing was a three-season or in some areas a four-season activity.

Among the land animals, caribou were by far the most important source of food. Most groups took advantage of the great seasonal migrations, particularly those in late summer and fall. Men working together generally shot or speared the beasts from land or from kayaks as they crossed bodies of water or forced them, with corrals and/or stone cairns, into narrow places and shot them there. Other land animals used for meat and/or fur included musk ox, wolf, fox, wolverine, and squirrel.

In addition to food, caribou also provided the single most important source of raw material. From the caribou, and other animals as well, came clothing, shelter, bedding, boats, thread, and lines (sinew). The people made a variety of tools and weapons, such as harpoons, bows and arrows, needles, thimbles, knives, axes, adzes, drills, scrapers, and shovels, primarily from bone and antler. The defining women's tools, reflecting their main activities, were the ivory or bone needle, the semilunar, sinew-backed knife, and the stone skin scraper.

People used a number of chipped stone (flint, slate, or quartz) items, such as points, blades, pots, and scrapers. Some copper was also used around Coronation Gulf. Many people depended on soapstone (pottery in southwest Alaska) oil- or blubber-burning lamps with moss wicks for heat and cooking. Wood, mainly driftwood, might provide boat and house frames, boxes, tool and weapon handles, and dishes. Depending on the location, baleen could also be worked into boxes or other items. Other key technologies included movement indicators (for breathing-hole sealing), various types of harpoons (especially with detachable heads), throwers (atlatls), seal nets, bird bolas, three-pronged spears, fishhooks, stone fish weirs, and small animal traps and snares. Most people started a fire either by striking two pieces of pyrite or by friction generated with a thong drill.

Chipped stone work was well developed among the Native Arctic people, but they were particularly adept at carving figurines, amulets, toys, and other items out of bone, antler, and ivory. Tailored clothing was decorated with finely sewn furs. Some groups, mainly in Alaska, carved and painted wooden ceremonial and dance masks. Baskets were particularly fine among the Unangan, but people in southwest Alaska and in Labrador made them as well. In some areas, music and storytelling were considered high arts.

■ Introduction: Urbanization

By 1000 BCE, urban centers are the most powerful hubs throughout the world. While much of the world's population continued to live in rural areas, the city became

the center of economic, political, religious, and social life for most of the civilizations of the world (the people of Oceania being a major exception to this).

One of the most significant changes to urban life is that urban planning became much more sophisticated in the period from 1000 BCE to 300 CE throughout the globe. Whereas the first cities (located in the Near East) were built on an almost ad hoc basis, with planning occurring gradually in relation to preexisting structures, by 1000 BCE there develops a tendency to conceptually organize the city before construction begins. In some cases this may have involved very detailed planning and zoning. In most cases, however, this would involve establishing a few cardinal points and perhaps a basic grid in which builders would have to work.

In the Near East, the Assyrians (an empire based in what is now known as northern Iraq) would level cities that they conquered and rebuild them on orthogonal plans. After Assyrian power had vanished and Greek civilization was flourishing, Hippodamus of Miletus (498–408 BCE) established a type of city grid plan that was emulated by the Greeks and Romans for centuries. As Roman civilization expanded be-

yond the city of Rome and colonies were constructed, these colonies were built according to strict organizational principles. Rigidly planned cities were also built in the Americas around this time. Olmec ceremonial centers were built according to cosmological principles, and later Mesoamerican cities, such as Teotihuacan, were structured similarly.

—Kevin M. McGeough

Meroitic Cities

At the height of their power, the kings of Meroe ruled over a population of an estimated 500,000 individuals. Many of these subjects continued to live in simple reed huts and shelters; others lived in more durable houses of mud brick, the rectangular floor plans of which usually contained two or three rooms.

There is little evidence for town planning. The settlement at Karanog, which covered a maximum surface area of about 20 acres (80,000

THE TEMPLE COMPLEX AT MUSAWWARAT ES-SUFRA

The most unique sanctuary in Nubia is doubtless the complex at Musawwarat es-Sufra. Its confusing ground plan led earlier scholars to reach erroneous conclusions about its function, claiming that this complex in its distinctive enclosure was either a Meroitic queen's summer residence, a theater for the training of elephants, a secular educational complex, or a seminary for Meroitic priests. One now realizes that the complex in its present state is the result of the rebuilding and modification over time of a pilgrimage center. The focal point of the center consists of at least seven temples, three of which are located within the Great Enclosure, one of these having been erected on a terrace. These are surrounded by a maze of courts and individual rooms of varying size, some of which are connected by a network of corridors.

The so-called Great Temple within the enclosure at Musawwarat es-Sufra was erected on an elevation. Its principal facade abandons the twin towers of the pylon in favor of a shrine-shaped entrance, crowned with a series of cavetto cornices, each decorated with its own winged sun

disk, which is set into a long, proportionately not very tall wall. Its design appears to recall that of the facade of the second story of the Lake Edifice of Taharqa at Karnak. This was fronted by a series of remarkably designed columns, the shafts of which feature sculpted decoration erected on bases in the form of animals. Monumental statues of Meroitic gods, suggested to have been Arensnuphis and Sebiuemker, flanked the entrance on the model provided by ancient Egyptian temples. A unique detail was a wall projection depicting an elephant. Behind the colonnade of the facade was a one-chambered sanctuary surrounded by a columned ambulatory. Its roof was supported by four interior columns, and its interior walls were provided with niches, perhaps for statues. Its facade and two lateral walls contained doorways as well, but the rear wall did not. Its ground plan, although unusual, appears to have been specifically designed to accommodate efficiently the circulation of pilgrims. There is no indication, however, of the deity to whom this innovative sanctuary was dedicated.

—Robert S. Bianchi

square meters), was home to an estimated 4,000 residents. A description of the town does not seem to differ from that of contemporary rural villages in Roman Egypt, such as Karanis (Kom Ouchim). The streets were not laid out in any perceptible, predetermined pattern, but meandered as if at will and resembled narrow alleys. The houses were constructed of a variety of materials, the use of which was doubtless a reflection of wealth and status, which included mud brick, stone, and rubble, with an occasional mud-brick veneer. Mud-brick houses consisting of three stories are still regarded by the inhabitants of the region as castles or palaces but were, in all probability, the residence of the most elite member of society, whom some identify as a “governor.”

Larger settlements, such as that of Kawa with its 8,000 inhabitants, are worthy of designation as towns, and the 24,000 residents of Meroe justify its designation as a city. Despite the size of these last two urban areas, the archaeological remains are not sufficient for one to present even a cursory description of the dwellings. Occasionally a site such as Wad Ban Naga provides sufficient remains of a royal complex to warrant comment. Here was found the residence of Queen Amanishakheto and several temples. Her mud brick palace is one of the largest identified to date. It measures some 200 feet (61 meters) in length and covers an area of nearly 40,000 square feet (3,700 square meters). The ground floor contained over 60 rooms for various purposes. This palace originally had a second story as the remains of columns found on the ground floor indicate, and this may have contained an atrium, a design feature paralleled elsewhere.

Israelite Cities

A distinctive vocabulary of royal architecture can be observed in the archaeological record of the Iron II period (1000–600 BCE). Typical features include casemate walls, six-chambered gates, and Proto-Aeolic capitals; ashlar masonry using dressed stones represents an appropriation of the Phoenician royal style. Many of these elements have been observed at Megiddo, the seat of an administrative center during the tenth century BCE. Two large public buildings (1723 and 6000) at the site were probably palaces. Palace 1723 was part of a larger complex enclosed by a field-stone wall and piers of ashlar. It also had a four-chambered gate with stone Proto-Aeolic capitals, a feature considered a standard in royal Israelite architecture by many scholars. Other buildings display northern Syrian and southern Anatolian influences. The city also had a massive six-chambered gate, 60 by 66 feet (18 by 20 meters) built of ashlar, though the dating of the gate is uncertain. Near the gate, a wall built in the elaborate offset-and-inset style was found. Another structure at Megiddo, consisting of small individual units, has been the centerpiece of one of the great debates of southern Levantine archaeology.

There are questions concerning the dating of this feature, that is, whether it belongs to the tenth or ninth century BCE. Even more controversial is the interpretation of its function. It was initially said that the units represented royal stables, such as those ascribed to Solomon in the Bible, but others have argued that they were storage units.

Six-chambered gates have been discovered at a number of sites, including Hazor, Megiddo, Tel Ira, Lachish, and Gezer. Recently, some scholars, such as Niemann and Finkelstein, have downplayed the importance of these gates as evidence for state architecture, arguing that at the very least there are no grounds for attributing them to Solomon or to any specific king for that matter. The gates clearly had a practical purpose as part of the city's defensive works. The Gezer gate system included a platform atop the tower from which to defend the city against would-be intruders while providing a way to monitor movement in and out of the city. Furthermore, gates of the same style have been

THE ARCHAEOLOGY OF JERUSALEM

The Canaanite city of Jebus was first established sometime during the Middle Bronze Age, perhaps around 1800 BCE, on a low hill surrounded by the mountains of Judea. Located near the Gihon Spring in the Kidron Valley, Jebus was one of the first sites in a wave of settlement in the central hill country. The city probably served as a commercial center where people from nearby villages would congregate and as a central point in the long-distance trade networks emerging at the time.

The Middle Bronze Age occupation is attested by archaeological evidence, including a long stretch of wall dating to the eighteenth century BCE, and the city enters the historical record with its mention in the Execration Texts (ca. 1900–1800 BCE). In 2009 archaeologists discovered a section of an MBA wall that was 79 feet (24 meters) long and 26 feet (8 meters) tall outside the Old City of East Jerusalem on a slope of the Silwan Valley. One of the most intriguing and controversial topics in the archaeology of the southern Levant concerns the occupation of Jerusalem during the Iron II period. The beginning of the Iron II is generally understood to be the time when the biblical kings David and Solomon ruled from Jerusalem. Yet the archaeological evidence dating to this period is slim. Some scholars have cited the general lack of

archaeological remains from this period as evidence against the existence of a Jerusalem-based monarchy at that time, and the historicity of the biblical account has been called into question. Others have countered that this “negative evidence” proves little, as Herod (first century BCE) is supposed to have razed the entire area during his extensive building projects, wiping out the traces of earlier structures.

The density of modern occupation in this critical area of ancient Jerusalem as well as the current political situation have limited the amount of archaeological research on the Iron Age occupation. Nonetheless, a few outstanding archaeological features dating to this period have been excavated. On the eastern slope of the Iron Age city, archaeologists have uncovered a large stepped structure preserved to a height of about 54 feet (16.5 meters) that can be tentatively dated to the tenth century BCE. Though some have been tempted to associate this structure with David’s “fortress of Zion” (Metsudat Zion) as described in 1 Chronicles 11:5, it is more likely that it served as a retaining wall employed in the construction of the citadel. But where the early part of the Iron II is concerned, opinions about the history of the city vary widely.

—Jonathan M. Golden

found at Canaanite and Philistine sites (for example, Ashdod), raising questions about whether they should be regarded as unique to Israelite architecture.

Regardless of who was responsible for the construction of these monumental works, they suggest a number of things about Iron Age societies. Clearly, all of these monumental structures point to a developed urbanism, which is indicative of both population growth and agglomeration. They also reflect the command of extensive resources, including materials and, above all, labor. Politically, they contributed to the identities of these cities. Huge residential buildings served as palaces for local rulers, while other structures were the focal point of political and administrative activity. The massive walls and gate systems represent defensive measures as well as prestige architecture designed to project an image of prominence.

The key question with regard to these projects concerns to what extent they represent political integration at a broader level. That is, were they independent undertakings, or was the centralized state involved? David Ussishkin, excavating at Lachish (Level IV), ascribed the construction of the massive brick fortification wall and triple-chambered gate to a Judahite king, either Rehoboam or Jehoshaphat. Cities of the Negev, such as Arad, Beer Sheva, and Malhata, also had great walls and other monumental works in the late tenth and ninth centuries BCE, and it is likely that their construction was financed, at least in part, with state funds from Jerusalem.

Urban Fires in the Roman World

Ancient Rome was prone to gigantic fires that caused massive destruction over vast parts of the city, devastating immense sections and involving the loss of tenements, palaces, granaries, warehouses, and public buildings. Endemic urban fires in ancient Rome were prevalent due to its narrow streets and alleys along closely packed tenements made of flammable building materials. A lack of proper facilities for handling large fires also played a part in allowing these fires to break out uncontrollably over much of the city. Fire proved

to be a much more potent force of annihilation for Rome than the destruction caused through invasion and decomposition over time.

The great fire of 64 CE attributed to Emperor Nero is perhaps the most historically recognized of the destructive fires that plagued Rome. This fire began on the night of July 18 and lasted a full six days. The ancient allegation that Nero deliberately set this fire to create a backdrop for his musical performance is not accepted by historians as historical fact but rather is viewed as evidence for the disdain that ancient Rome felt toward this particular emperor. The subsequent casting of blame on the local Christian community to unleash state-sanctioned persecution, which resulted in the martyrdom of St. Paul and St. Peter, is also attributed to Nero. The ultimate effect of this fire was the destruction of huge parts of the central city, ultimately rebuilt under Nero.

The proximity of cultural, public, and commercial centers around the central parts of the city allowed the rapid spread of the fire throughout various districts of the city. The lack of an efficient fire department to stem the growth of such fires further contributed to the spread of the destruction.

The end result of these massive fires that plagued ancient Rome was the immediate rebuilding that resulted. Under various emperors, such as Augustus who "found the city made of wood and left it in marble," the fires presented an opportunity to rebuild the city along more efficient and beautiful lines. Many of these fires were particularly prevalent around the Circus Maximus, the Forum, the Campus Martius, and the Sacra Via. The constant plague of urban fires throughout Rome, while immensely destructive, was utilized as an opportune time to rebuild certain rundown areas.

Mediterranean Deforestation

Since the Mediterranean basin is diverse, which makes it difficult to talk about similar ecological processes occurring in this area since antiquity, recent archaeological and environmental data point to a trend toward deforestation caused by human activity. Farming and grazing over the past 9,000 years and demand for wood have required an alteration of Mediterranean landscapes. The steady proliferation of farming communities across the Mediterranean during the Late Neolithic marked the beginning of a continuous process of clearings and intense impact over the land cover, but many specialists argue that the most intense clearing performed by ancient civilizations in the Mediterranean basin occurred since the Roman Classic period, when agriculture became the basis of the empire.

However, the transition from foraging to farming economies during the Neolithic and the later stress caused by the Roman empire cannot be blamed as the root causes of major land clearings and the consequent deforestation of the Mediterranean. The uses of wood were also key to large areas of technological and economic development in antiquity prior to the Roman empire. Trees and timber were useful for the construction of ships; to build bridges, palaces, and other public buildings; and to make furniture and wooden statuary during the Bronze Age and the Iron Age in eastern Mediterranean societies. For example, the Old Testament and the Epic of Gilgamesh are among the first historical sources to talk about the social and economic importance of timber. Both texts mention the value of Lebanese cedar forests, not only admired for their beauty but also because they provided the timbers needed for the temples. Cedar and cypress were the most desired trees because of their fragrances. Phoenicians also provided the backbone of the Persian fleet, which was built from the forests of Cilicia, Syria, and Phoenicia.

We have several historical documents and archaeological and pollen data from the Roman Classic period. This information confirms that under the empire, agriculture continued to expand at the expense of the forest. Several au-

thors mention that the most spectacular expansion of agriculture was in the Roman province of Africa, an area that corresponds to present-day Tunisia, Algeria, and Morocco. This area, previously occupied by Carthaginians, was said to be sending sufficient grain to Rome to maintain a population of nearly one million people. The increase of production was due in part to more skillful management but also to the addition of new land.

Ceremonial Cities of Iran

Along with administrative practices, engineering techniques, and writing, the Achaemenid dynasty (550–330 BCE) appropriated and greatly adapted the use of art and architecture as a ceremonial stage from the cultures it incorporated. As opposed to other important cities in the empire such as Susa (which served as the empire's true administrative center on the lower Mesopotamian plain), Babylon, or Ecbatana in northwestern Iran, the Persian kings created and maintained two imperial capitals in the heart of the Achaemenid home province of Parsa (Persia). Located in southwestern Iran, Pasargadae and Persepolis appear to have fulfilled a more symbolic ceremonial function than the aforementioned older urban centers. Although we refer to them as “cities,” the palatial cores of Persepolis and Pasargadae dominated the sites' topography and significance. Persepolis survives in a greater state of preservation than Pasargadae and provides us more information, although archaeological and inscriptional evidence suggests that both were used through the end of the dynasty. The most prominent ceremonies that took place at these sites were royal audiences, large-scale military parades, tribute ceremonies, investitures, and religious and funerary observances.

The founder of the empire, Cyrus the Great (559–530 BCE), established Pasargadae. Two rectangular audience halls, a quadripartite garden with water channels provisioned with two pavilions, a gatehouse, a stone tower 13 feet (4 meters) high, and the masonry tomb of the king formed the main features of the palace of Pasargadae. The garden itself is the earliest surviving Persian royal garden, and its fourfold organization, as well as the presence of the king of kings dominating it, symbolized Cyrus's designation of himself as king "of the four quarters of world" (*Cyrus Cylinder* 11.20–21). The function of the tower (referred to by scholars by its New Persian nickname as the Zendan-e Solayman) as well as that of the nearly identical tower at the site Naqsh-e Rostam (the Kaba-ye Zardosht) is unknown, though a treasury, fire altar, temple, and ossuary have all been offered as interpretations. Nevertheless, the fact that it was replicated at Naqsh-e Rostam and parallels with earlier Urartian towers suggests that it was religiously significant. The monumental tomb of Cyrus, constructed on a high platform 10.9 feet (3.35 meters) long by 40.3 feet (12.3 meters) wide of ashlar masonry, lay 3,280 feet (1 kilometer) to the south of the palaces and garden and itself appears to have been the focus of ceremonial attention beyond just serving as the resting place of the dynasty's founder.

Originally a pretender to the Persian throne in the years of confusion after the death of Cyrus, Darius I (522–486 BCE) founded Persepolis once he consolidated power as an architectural expression of his newly developing royal ideology. Persepolis lies about 37 miles (60 kilometers) northeast of the modern city of Shiraz on a vast plain and is built against a rugged mountain range. Rising as much as 46 feet (14 meters) on an artificial terrace from the plain below, the precincts of the palace cover an area 1,476 by 984 feet (450 by 300 meters). Some architectural features in the site, such as the audience hall and gatehouse, can be traced to precedents at Pasargadae; however, Persepolis presents a much grander, coherent, and developed manifestation of Achaemenid art and architecture, which took form under Darius I.

The ceremonial core of the palace was founded around a grand audience hall (Old Per-

➤ PALACE AS A PREFIGURATION OF A WORLD RENEWED

Palace building was not only an architectural and engineering achievement in the eyes of the Achaemenid kings but was also a religious achievement. According to Darius's Susa inscription, workers from all over the empire brought what was best from their land: cedar from Lebanon, gold from Lydia and Bactria, silver and ebony from Egypt, etc. In assembling the whole, the palace becomes a divine vision of what is best on the earth. In fact, Darius uses a word in Old Persian to describe his palace, *frasha* (a wonder), that is intentionally the same as the one the Avesta uses to describe the Great God's postapocalyptic renovation of creation.

—Matthew Canepa

sian: *apadana*) measuring 1,173 square feet (109 square meters) raised on an 8.5 foot (2.6 meter) platform, although the site eventually contained a multitude of public and private structures. At 62.3 feet (19 meters) high, the 36 stone columns of apadana would have given the interior the effect of a forest of columns. An elaborate composite capital crowned the columns, with symmetrical bull capitals marking the external porticos and main hall.

Persepolis's apadana presented three ritually significant focal points, both from the point of view of the king of kings and any potential military or diplomatic spectators. In all three cases a six-column portico performed as both a dramatic backdrop for the king of kings enthroned and ritual interface with those gathered in audience. The western portico of the apadana looked outside of the palace grounds over the plain below. This provided an elevated vantage point for the sovereign to view military parades below and for an assembled multitude to behold the king of kings in glory. Those lucky enough to gain entry to the palace were compelled to ascend a ceremonial way that led onto the platform up a double switchbacked stairway and then into the palace grounds through a monumental gateway flanked by composite enormous human-headed winged bulls. The inner faces of the apadana—that is, the north and east faces—fronted an

internal L-shaped courtyard, each provided with a symmetrical double stairway richly embellished with relief sculpture. The interior of the apadana and the private palace (Old Persian: *ta-cara*) of Darius to the south potentially offered successively more intimate ceremonial venues for royal audience and entertainment.

What we know securely about Persepolis's ceremonial usage comes almost entirely from the surviving relief sculptures that cover its lower walls. The fronts of mirror-image apadana stairway reliefs portray representatives of all peoples subject to the Persian empire identified through inscriptions and distinctive dress, bearing gifts to the Persian king. A Persian or Median courtier leads the leader of each of the 23 delegations by the hand. Row after row of Persian soldiers flanked the rear of the stairway, reinforcing the idea that this vision was created because "a Persian man's spear has gone far," as Darius I claims in his inscriptions (*Naqsh-e Rostam*, A 41–47). Much like the actual presence of the king of kings, the central image of a king of kings enthroned with his son and successor behind him was the focal point of the northern apadana stairway. The reliefs are the only Iranian sources on such a tribute ritual; however, Herodotus mentions that the Persian kings constantly demanded that the Greek city-states bring him "soil and water" as a ritualized token of submission. In the last century, the archaeologist Roman Ghirshman conjectured that the Achaemenids constructed Persepolis for an elaborate ceremony that took place in conjunction with the spring celebration of the Iranian New Year; however, while it has often been repeated, this theory lacks any evidence to support it. The tribute bearers could just as likely reflect a composite vision of delegations that visited the king of kings (either in Persepolis or elsewhere) severally rather than in a single ceremony. In either case, the overall effect is the same. The apadana sculptures reflect a world, both its human and material components, that the king of kings has ordered and melded into a harmonious whole, a terrestrial reflection of the god Ahura Mazda's divine work.

While Persepolis had a special symbolic role in the Persian heartland, the palaces of Susa and Ecbatana had their own ceremonial significance

too, as evinced by the remains of apadanas with similar features and, in the case of Susa, similar measurements as Persepolis. Both were built at sites that had been the capitals of peoples held in high esteem by the Persians who had been incorporated into the empire. Susa had been capital of the Elamites, and Ecbatana had been capital of the Medes, and with the creation of an apadana at these former imperial capitals, the Achaemenids put a distinctly Persian stamp on the urban fabric. While Ecbatana has not been well studied, from the extensive excavations at Susa we learn that the palace there had an artistic program similar to that of Persepolis. Executed in brightly colored glazed brick rather than relief sculpture, the dominant programmatic theme consisted of tribute bearers from all over the empire, Persian and Median courtiers and soldiery, and fantastic composite creatures.

Given their close proximity to palatial and religious structures, the royal tombs in Parsa were themselves important ceremonial centers dedicated to the memory of the kings of kings and, in the case of Pasargadae, were used for investiture ceremonies. Beginning with Darius I, the majority of the Achaemenid kings of kings created their tombs at the site of Naqsh-e Rostam, which lay about 5 miles (8 kilometers) from Persepolis. Later in the dynasty, three other kings carved theirs at Persepolis. Naqsh-e Rostam's Achaemenid remains consist of four identical rock-cut tombs and a tower constructed of finely dressed ashlar masonry called the Kaba-ye Zardosht ("Kaba of Zoroaster"), itself identical in plan and size to the Zendan-e Solayman at Pasargadae. Like the apadana, the visual program of the tombs presented a vision of "the world as it ought to be" to Persian and subject alike. In the upper register, the king of kings stands on a throne (Old Persian: *gathu*) before a fire altar, raising his right hand in respectful address to a winged divine figure symbolizing the Great God Ahura Mazda. Below, figures of all the peoples of the empire, identified by distinctive dress (and in the case of Darius I's tomb, an inscription) support the throne with their upstretched arms, while Persian soldiers stand at attention on the flanks. Darius I's tomb contains a monumental trilingual inscription carved on its surface, which commands the viewer to behold the images if he

should wonder—"How many were those lands which Darius the king holds?"—and orders him to "See the images which bear the throne. There you will learn, it will become known: A Persian Man's spear has therefore gone far" (Darius, *Naqsh-e Rostam* A 41–47). Although not contemporary, the Hellenistic historian Arrian (*Anabasis* 29.1–11) states that up until Alexander's invasions, Magi tended the tomb of Cyrus at Pasargadae, offering a sheep and a measure of grain daily as a sacrifice for his benefit. Again, according to Greek historians, succeeding Persian kings would receive their investiture at Pasargadae, where they would eat a ritual meal and ceremonially don a cloak that had belonged to Cyrus (Plutarch, *Artaxerxes* 3.1–2; see also Xenophon, *Cyropaedia* 2.4.1, 8.1.40–41, 8.8.15; Herodotus, 1.135). A monumental stone plinth and altar found at Pasargadae are likely the physical remains of the ritual portrayed on the tombs' upper panel, which represent the king on a platform venerating a fire altar. It is probable that the Achaemenid sovereigns performed such ceremonies of public fire veneration in front of an audience of assembled armies and courtiers as a public display of piety and divine favor.

Following Alexander the Great's conquest of the Achaemenid empire, the traditions of the Persian ceremonial cities were radically disrupted as Hellenistic ideas of urbanism and royal rituals, as well as new city foundations, supplanted those of the Achaemenids. Persepolis was the site of several impromptu ceremonies on the part of the Greeks, the most infamous of which was Alexander's destruction of the palace complex after victory games and a banquet at the site in 330. Although Diodorus Siculus (17.20–22), the source who records the event, presented the conflagration as a spontaneous drunken event, done in "revenge" for Xerxes' destruction of Athens, it surely was not done without Alexander's approval as a means to obliterate this site, which was so symbolic of Achaemenid power, especially considering that Darius III was still alive and a threat at the time. In an interesting reversal of policy, once Darius III had been killed, Alexander began to associate himself with the Achaemenid dynasty, including modified court ceremonies and care for symbolic structures such as the tomb of Cyrus.

After Alexander's death, one of his companions, Peucestas, whom he had appointed governor of Parsa, chose Persepolis to stage an elaborate banquet for his army and conducted lavish sacrifices to Alexander and Philip II under its shadow (Diodorus Siculus, 19.22–23). The site's prominence and ceremonial role, however, were permanently eclipsed by the new foundations of the Seleukids (312–64 BCE), the Hellenistic dynasty that held power over Iran after the death of Alexander, although later regional Persian dynasties continued to marvel at the ruins and sponsor small-scale interventions on and near the platform. Seven centuries later, under the Sassanian dynasty (224–642 CE), Naqsh-e Rostam again became a focus for royal ceremonies and was instrumental in forging connections between the dynasty to its ancient—though imperfectly remembered—Persian heritage. Six kings and one cleric sponsored monumental rock reliefs directly underneath the Achaemenid tombs. Shapur I (r. 239–270) carved a trilingual inscription on the Ka'ba-ye Zardosht that described the foundation of sacred fires "for the soul and memory" of himself and his family (Shapur I, *Ka'ba-ye Zardosht* 33–34). The sites' most recent use for large-scale ceremonials occurred in 1971 when Reza Pahlavi staged massive and expensive spectacles at Pasargadae and Persepolis for the world's heads of state in hopes of associating his short-lived dynasty with the glories of the Persian past. Ironically, these ceremonies have often been marked as the beginning of the end of his regime, overthrown in the revolution of 1979.

Urban Features and Foreign Influences in Gandhara

Gandhara, in northwestern South Asia, was a cosmopolitan region in ancient times, culturally both part of South Asia and an international melting pot. For a while it formed part of the Achaemenid empire; subsequently the region fell to Chandragupta and was incorporated into the Mauryan empire that he created, which reached its peak under his grandson Aśoka. When the Mauryas declined, Gandhara passed to the Indo-Greek kings who controlled the eastern remnants of Alexander's empire, after them to Shakas (Scythians) and Parthians from western central Asia and Iran, and finally to the Kushans, originally central Asian nomads, who gained control of much of northern India. Gandhara lay across major trade routes, from the West going south to Indian cities and east to China and up the Indus from the Indian Ocean and beyond. It was therefore open to influences from people of many nations.

These influences are apparent particularly in Gandharan art and architecture and in the mixture of religions represented by shrines in its cities. At Taxila, for example, these included a probable Zoroastrian fire-temple as well as small Buddhist, Jain, and Hindu shrines. A statue from Taxila depicted the Egyptian child-god Harpocrates, and other sculptures also reflected religious plurality.

Taxila, capital of the Mauryan northern province, well illustrates the interplay of native and foreign urban forms. The first city, known today as the Bhir Mound, was founded or expanded by the Persians around 400 BCE; little of this (Period IV) has been exposed. A rubble wall probably originally surrounded the city but has since been robbed out. More recent deposits belong to the later period of Persian control and the early Mauryan occupation (Period III) and to the later Mauryan period (Period II). Excavations of part of the Mauryan city reveal a straight main street with irregular blocks of housing and side streets off it. Two other major streets, roughly parallel to the first, are narrower and far from straight, and the end of one is blocked by houses. The houses themselves are irregular in size and layout, the basic plan consisting of a courtyard and

a number of rectangular rooms. Narrow soakwells were a regular feature of the houses.

This both resembles and contrasts with the cities of the Mauryan heartland in the Ganges Valley. Soakwells were a usual feature of these cities. The houses in cities such as Bhita had similar but more regular plans, and the streets were laid out straight, following cardinal directions. This more closely matches the ideal prescribed by Kautilya in the *Arthashastra*: a square city with a fortification wall and four gates, divided by straight regular streets leading to the center where religious buildings should lie, flanked to their north by the royal palace.

The Indo-Greeks at first occupied the Bhir Mound (Period I) but soon moved to a new site, Sirkap, where they laid out a walled city (levels 6–5) in Greek style following a formal grid plan with straight streets crossed at right angles by smaller side streets that divided the buildings into blocks. This plan was preserved in later periods under the Scytho-Parthians (levels 4–3) and Parthians and Kushans (levels 2–1). Excavations were concentrated in the two upper levels where, for the most part, the blocks of buildings consisted of houses of one or more courtyards surrounded by rooms. Ground-floor rooms were used as cellars or basements or were filled in as solid supports for the main occupation level on the first floor, the level at which one entered the house. Often the house had a small shrine on its street front, accessible to the public from the street. Other small rooms in front of the houses may have functioned as shops. One block was entirely taken up by a courtyard housing an apsidal shrine containing a stupa. Several other blocks were large complexes of courtyards and public and private rooms, probably the mansions of wealthy citizens, the largest possibly a royal palace. The structures in Sirkap show a blend of Indian and Greek features: the general grid layout of the city and many decorative elements, such as pilasters, were of Greek inspiration, but the courtyard layout of the houses and their construction with flat mud roofs supported by timber beams followed long-established Indian traditions. The acropolis on the Hathial ridge, separated from the lower town by an internal wall, was also a standard feature of Greek

town planning, although not without local antecedents. Structures excavated here include several stupas as well as courtyards and rooms that may have belonged to a palace.

Outside the successive cities (including a third, Sirsukh, built by the Kushans in the late first century CE but largely unexcavated) the Taxila Valley had many Buddhist religious complexes as well as a few shrines of other religions. This again follows the ideal recommended in the *Arthashastra*, which mentions religious settlements as one of the urban features that should be located outside the city walls; others include cemeteries and gardens. Many of these complexes were located in small valleys or on leveled hilltops, at once secluded to encourage religious contemplation, and within easy range of the city to enable the monks to beg alms. The complexes varied in size and detail but usually were comprised of a stupa and a monastery. The main stupa was usually located in the center of a walled courtyard, with small chapels around its walls housing small stupas, or stucco reliefs or statues of the Buddha, often flanked by attendants. Sometimes other small stupas were placed adjacent to the main stupa. A number of the stupas in the Taxila Valley were founded by the Mauryan emperor Aśoka and later enlarged. Pre-eminent among these is the Dharmarajika stupa, part of a large complex around 2 miles (3.2 kilometers) from the Bhir Mound.

Beside the stupa courtyard, and often opening from it, was the monastery. This had a main courtyard surrounded on all four sides by the individual monks' cells. A stair led to another range of cells on the upper story. Wooden pillars supported a veranda on both levels. Often a large square depression, lined with stone, in the center of the courtyard caught the rainwater running off the veranda roof; from here it could be drained away or used as a reservoir. A bathroom was often positioned at one corner. The cells were very plain but had a high window and often a niche in which an image could be placed. A doorway or passage from one side of the courtyard led to a further suite of rooms: the Assembly Hall where the monks met to pray, hold discussions, and listen to sermons; a kitchen with store-rooms; and the refectory where the monks ate.

➤ CHARSADA

Situated in the Vale of Peshawar, Charsada (ancient Pushkalavati), like Taxila, lay at a cross-roads for trade routes. Here occupation began in the fourteenth century BCE on the Bala Hissar mound as a settlement of post-built and later mud-brick houses, perhaps surrounded by a small ditch. Incorporated into the Achaemenid empire from 518 BCE, Charsada became the capital of Gandhara Province. A massive fortification ditch and rampart around the mound probably dates to this period. This was later superseded by a substantial retaining wall. Little of the city's interior has been investigated. The city's fall to Alexander is recorded by Arrian.

The Indo-Greek settlement at Charsada, on the Shaikhani Dheri mound, was probably founded in the second century BCE and has a similar layout to Taxila. Within city walls now visible only as robber trenches, the city was laid out in a grid of straight streets with a Buddhist shrine at the center. This layout was preserved in the later, Kushan, occupation of the settlement. One house here, which follows the usual arrangement of a courtyard with surrounding rooms, included a bathing place in the courtyard; it was rebuilt and modified several times, finally being remodeled as a Buddhist temple complex. Eventually extensive flooding drove people from this site to settle on the other side of the Zinde River on what is now the Rajar Mound.

—Jane R. McIntosh

Similar monastic complexes were constructed the length and breadth of South Asia. Initially simple huts sheltered monks and nuns during the rainy season, but already by Mauryan times monasteries were more permanent and substantial establishments, attracting the generosity of lay devotees, from craftsmen to kings, who provided gifts of money to pay for buildings, goods such as cloth for the monks' use, and money and land to support them. Royal grants of land might also include the labor of its inhabitants, who would undertake day-to-day tasks for the monks. By the first century CE many monasteries were wealthy. As well as offering charity to those in need, from individuals suffering personal

distress to whole communities suffering famine, monasteries had a prominent role in trade and industry, providing venture capital and a safe depository for goods as well as hospitality to travelers. Many monasteries lay on major routes. Those of Gandhara were no exception since the region was a major crossroads for international trade, something that is reflected in the diversity of goods recovered from hoards in the cities. These were buried at times of trouble. The last, the invasion of the White Huns in the later fifth century CE, is vividly attested by the evidence of burning and destruction throughout the secular and monastic buildings of the Taxila Valley.

Central Asian Commercial Cities

Many commercial centers developed in central Asia on or near the major Silk Roads routes, the inter-Eurasian trade routes that linked China with the Mediterranean. Besides serving as markets, commercial cities provided merchants with supplies, money changers, warehouses for goods, new transportation, lodging, food, religious centers, entertainers, and prostitutes. These Silk Roads cities were located near a source of water, be it a river, spring, or man-made water source. Freshwater supplies were so important that in some areas under Chinese control bamboo pipes were used to bring water from the mountains to the trade route, or *kariz* were built to move water underground to cities, towns, and garrisons.

Cities also grew up near sources of production or local resources, such as jade from Khotan or mineral resources along the Northern Road of the Silk Roads. Others developed around religious centers or grew up around garrisons or centers of administration. Documents found at Turfan, also on the Northern Road, show the types of materials that were traded and taxed by weight including turmeric, gold and silver, am-

THE CITY OF LOULAN

Loulan is typical of cities along the northern Silk Roads. Located near Lop Nor in China's Xinjiang province, the region was an extensive oasis until the fourth to fifth century CE. Loulan was laid out on a grid pattern and surrounded by walls from 3 to 15 feet (1–5 meters) high and 1,300 feet (400 meters) long. The walls had four gates, one on each side. The city was divided into three sections with religious structures in the northeast, government buildings south of the center, and a residential area in the southwest. In the third century CE the Chinese built fortifications and established an administrative center in Loulan to ensure the safety of travelers and merchants. The Chinese withdrew early in the fourth century CE when the region underwent an environmental change. It became more arid, and Lop Nor became alkaline as the rivers supplying the lake dried up.

(Shupeizhang)

monium chloride (used as a flux to help with fusion in metalwork and as a mordant that fixes colors in dyeing), brace, medicines, and sugar.

Farther west there were other major commercial centers such as Kashgar in the present-day Chinese province of Xinjiang. This city was at the crossroads where the northern and southern routes converged. In present-day Uzbekistan, the cities of Bukhara and Samarkand were trade centers from its founding around 700 BCE. Alexander the Great reached the city of Samarkand in 328 BCE when it was known as Marakanda. Samarkand also served as the summer capital of the Sogdian empire, and for part of its history Samarkand was called Sa-mo-kien and was the westernmost province of China. Other major cities included Merv, Herat, Balkh, and Termez. Many cities that were active during the period of trade along the Silk Roads still exist today, showing the continued importance of their location.

Cultures in Central Asia, 1000 BCE–300 CE

Eurasia, the combined landmass of Europe and Asia, is a physiogeographic concept, while Inner Asia (interior Eurasia) includes central Asia, Siberia, and the nomadic cultures that inhabited the area from China through contemporary eastern Europe. Historically, Inner Asia incorporates the civilizations of central Asia, Mongolia, Tibet, and adjacent areas and cultures that during certain prehistoric and historic times had cultural, political, or linguistic affiliations with these regions. Central Asia's frontiers have shifted through time, varying according to the balance of power between the civilizations of Southwest Asia, the Asian subcontinent, and Southeast Asia. The most commonly used definition is that central Asia covers about 3.47 million square miles (9.03 million square kilometers), or 21 percent of the continent, and includes the region from eastern Europe, Belarus, and Ukraine on the west side; the

Chinese provinces of Sinkiang, Xingang, and Qinghai on the east side; Mongolia to the northeast; Siberia to the north; and the Indian Ocean to the south. Another definition includes the Transcaucasian countries, Iranian Azerbaijan, the Turkic-Muslim regions of southern Russia, Afghanistan, northern Pakistan, and southern Siberia. A third definition considers central Asia as comprising only the five former Soviet central Asian republics. Recent archaeological research focusing on the periods since 3000 BCE has led scholars to propose the term "Middle Asia," which includes the region bounded by Southwest Asia, southern Siberia, China, and the Indian Ocean that was home to a number of early civilizations.

Middle Asia is thus a geographically complex region of high plateaus (Iranian Highland) and high-altitude mountains, most of the latter running east-west (Kopet Dag, Hindu Kush/Paropamisos/western Himalayas, Pamirs, Turkmen-Khorasan, Tian Shan), vast deserts (Dasht-i Margo, Dasht-i Luft, Kara Kum, Kyzyl Kum, Taklamakan), and treeless grassy plains or steppes and semideserts rich in flora (Turkistan Plain, Ferghana Valley). The primary rivers include the Amu Darya (Oxus), Syr Darya (Jaxartes), Vakhsh, Murghab, Helmand, Hari Rud, and Kabul/Upper Indus; the major bodies of water are the Aral Sea and Caspian Sea to the west and the centrally located Lake Balkhash and Lake Issyk Kul.

From 1000 BCE to CE 300, central Asia played a significant intermediary role in the transmission of culture, languages, religions, ideas, and artifacts east-west and north-south. The dates and geographical distributions for this vast, culturally complex area's cultural periods are derived from archaeological data and evidence from architecture, epigraphy, numismatics, burials, and hoards. There are no reliable written sources for the region prior to the Achaemenids.

The rise of chiefdoms or kingdoms and states accompanied by urbanization during the Bronze Age occurred in the region from the Indus to the Oxus and into eastern Iran. Cities and smaller settlements show marked evidence of social stratification (notably variations in housing and burial practices), craft specialization, and intensive trading between the different areas at the same time as the spread of Indo-European

➤ CENTRAL ASIAN CULTURAL PERIODS TO 450 CE

languages. The vast Eurasian steppes from the Carpathian Mountains to the Altai included diverse livestock-breeding nomadic tribes and ethnic groups.

At the beginning of the first millennium, horse-riding pastoral nomadic tribes (such as the Karasuk) practiced seasonal transhumant migrations and participated in economic symbiosis with settled cultures. The first third of the first millennium BCE (early Iron Age) is associated with considerable economic diversity as seen in the wide-scale introduction of ferrous metallurgy, which contributed to specialized craft production including weapon making (notably in Transoxiana and the Chust and Dahistan cultures). Sedentary communities expanded oases

and irrigation cultivation, constructed monumental architecture, participated in overland caravan trade (especially along the Silk Roads), and witnessed the accumulation of wealth by the elite and nobility. The period between 700 BCE and 250 to 300 CE is characterized by the movements of populations; the continuation of local economic traditions in Parthia, Margiana, and Bactria; and the interrelations of their cultures in this region with the emergence of several nomadic and sedentary civilizations occupying parts of both the steppe and oasis zones. Groups of armed riders emerged from these nomadic tribes and initiated military conflicts with sedentary settlements that in turn led to the institutionalization of power, and tribal leaders often became absolute petty rulers. The horse-riding pastoral nomadic Scythians, or Scyths, were confederated tribes that occupied areas of the central Asian steppe from the Urals to the Altai Mountains from the eighth century BCE to 600 CE. The Persians called the Scythians “Saka,” but the term “Scythian” has sometimes been misapplied and has also been used to designate many horse-riding steppe cultures.

The contrast between the nomads and sedentary farming cultures was accentuated by the rise of the Achaemenid Persian empire, which extended from Egypt and Turkey through Afghanistan and was divided politically into administrative tribute-paying units called satrapies. The central Asian satrapies included Parthia (eastern Iran); Aria (western Afghanistan); Bactria (northern Afghanistan); Drangiana (the lower Helmand Valley and Seistan); Arachosia (the upper Helmand Valley and Kandahar); Sattagydia, later called Paropamisadae (the areas of Kabul, Bamiyan, and the Panjshir valleys); Gandhara (Jalalabad and Peshawar); and Gedrosia (Pakistani Baluchistan). Chorasmia, located northwest of Bactria and south of the Aral Sea, became an Achaemenid satrapy before 522 BCE and was an independent kingdom by 330 but later became a Parthian satrapy. Sogdiana, a politically divided Achaemenid province situated between the Amu Darya and Syr Darya, was a rich land of farmers and traders centered at the modern city of Samarkand. Margiana (Margu) was another Achaemenid satrapy centered at modern Merv by 515 BCE.

The defeat of Darius III at Gaugamela in 331 BCE by Alexander the Great transformed central Asia as the Greeks conquered Bactria and Sogdiana (330–327 BCE) and swiftly secured most of Afghanistan, Swat, and Punjab (327–325 BCE). The Greeks established a series of Hellenistic cities named for Alexander: Margiana (Merv), Aria (Herat), Arachosia (Kandahar), ad Caucasum/Kapisa (near Begram), and Oxiana (Eucratidia/Ai Khanoum). The nomads were expelled or integrated, and sedentary civilization was strengthened and became rapidly predominant. Hellenistic Seleucid kings controlled the provinces of Parthia and Bactria, but following the brief rise of the Graeco-Bactrian kingdom, a resurgent Parthia regained the western Graeco-Bactrian territories. During this time the civilizations of central Asia underwent a significant change whereby a progressive religious syncretism among Zoroastrianism, Greek beliefs, and Buddhism developed that would influence subsequent central Asian civilizations up to the Arab conquest.

Beginning around 160 BCE, Yuezhi and Saka tribes migrated westward from Sinkiang into the Pamirs, Herat, Seistan, and territories north of the Hindu Kush. During the first century BCE the Saka established kingdoms in eastern Iran and northwestern India, but in the first century CE these territories came under Parthian jurisdiction so that the Parthian empire incorporated eastern lands from Sistan to the Indus and absorbed the Saka by 100 BCE. Subsequently, the Indo-Parthians from the Indus Valley and Punjab under King Gondophares extended their control over Seistan, Arachosia, and Paropamisadae (20–80 CE).

The Kushan empire, which had Greco-Roman influence (seen in Gandharan sculpture, Buddhist art, and Kushan coinage), emerged to precipitate the collapse of the Parthians and annexed their subcontinent provinces. Prosperous long-distance caravan trade extended from the Mediterranean and China through central Asia via the Silk Roads. Despite the development of the sea routes, this intercontinental set of overland commercial highways continued for centuries. By 234 CE the powerful Persian Sassanians challenged the Kushans, and the Kushan empire disintegrated; the subsequent history of the Kushano-Sassanians in central Asia is obscure.

Biskupin—Poland's Pompeii

The site of Biskupin is located in Bydgoszcz Province in northwestern Poland. It is an early-Iron Age fortified settlement belonging to the late Lusatian culture and dates to approximately 750–550 BCE. Biskupin is the country's best known archaeological site both within Poland and outside of it.

The settlement at Biskupin was situated on an island, defended by timber breakwaters, and fortified by ramparts of timber compartments filled with earth and stones. The earth embankments were usually built on a foundation of beams and secured by vertical piles. The gateways to the settlement were an important part of fortifications, and the main feature of each was an approach that was lined on both sides by massive palisade walls and was probably covered on the top.

The settlement inside was constructed according to a plan, with a regular network of streets and communication tracks. The main arterial road was the street leading around the ramparts, and there were eleven parallel streets perpendicular to the arterial road. There was a small square near each of the gateways. The settlement consisted of 104–106 rectangular timber

MULTIDISCIPLINARY EXCAVATIONS AT BISKUPIN

The fortified settlement of Biskupin was found in 1933 and excavation began in 1934. Fieldwork was directed by Józef Kostrzewski and Zdzisław Rajewski. Excavations were carried out in the years 1934–1939, and when they resumed in 1946 after World War II, they continued until the 1960s. Various specialists from complementary disciplines participated: soil and geological studies, palynological analyses, botanical and dendrological studies, and ethnographic research of the Biskupin architecture. Photographic documentation of the site was very important. Wojciech Kocka developed the technique of taking pictures from a small balloon, and there were very successful attempts to produce color photographs as early as 1939.

Research at Biskupin marked enormous progress in Polish archaeological studies. It was truly comprehensive, owing to the fruitful cooperation with specialists from other disciplines. This cooperation was characterized by real partnership, and it led to the development of new methods of excavation. The large scale of the research was also significant. After World War II, Biskupin was the place where practical courses on excavation methods for students of archaeology, history, and the history of art were organized. As a result, the great majority of students of that time gained their archaeological experiences in Biskupin. Biskupin is now a well-known archaeological open-air museum. It was, and still is, an important center for experimental archaeology, especially in building, tillage, food preparation, stone and flint work, antler and bone work, wood and wool work, clay processing, and the obtaining of tar.

—Arkadiusz Marciniak

houses laid out on a regular street system, and they may have housed up to 1,000 people. Each house interior was divided into two parts with the entrance fulfilling economic functions. Two phases of occupation have been distinguished, and 75 percent of the site has been excavated thus far.

Olmec Ceremonial Centers

The ancient Olmecs occupied the Gulf Coast of Mexico, specifically parts of the present-day states of Veracruz and Tabasco. Between 1000 and 400 BCE, they erected structures at La Venta, Laguna de los Cerros, and, toward the end of the period, Tres Zapotes. Recently discovered residential units have altered the original conception of the empty Olmec ceremonial center, used only for ritual purposes. Indeed, these sites are among the earliest instances of urbanism in Mexico. La Venta, located in Tabasco and occupied for the entire period, exemplifies a uniquely Olmec adaptation to a swampy environment and the development of centralized sacred space. The sheer size and placement of La Venta's ceremonial center indicates its importance, as does the evidence of long-term modification and rebuilding.

Many raised platforms and open plazas characterize La Venta, but a large undulating pyramid clearly separates the ceremonial center from the rest of the site. This man-made mountain adjoins two contiguous rectangular plazas lying to the north. Long low-lying platforms flank the first plaza on either side. Large mounds bound the plaza to the north and guide movement into the second smaller plaza, also enclosed by mounds.

Access to this area was highly restricted, solidifying the sacred nature of the space in contrast to the other open and thus more public plazas located throughout La Venta. Offerings, such as massive mosaic pavements, were buried under the ceremonial plaza floors and may refer to a watery underworld; although never seen after interment, the mosaics further sanctified the area. Additionally, the site's north-south axial orientation, dramatized by bilateral symmetry, adapted to the surrounding topography through

an alignment with the large mountain to the south.

The La Venta landscape of sacred space can be found at other sites outside the Olmec's Gulf Coast heartland. In central Mexico, roughly contemporaneous with La Venta, non-Olmec people inhabited the sites of Chalcatzingo, Morelos, and Teopantecuanitlan (originally Tlacozoltitlan), Guerrero. Both reflect Olmec organizational patterns. They occupy a series of terraces and, like La Venta, include ceremonial cores oriented to the natural geography: at Chalcatzingo, the ritual center occurs at the base of a mountain, while Teopantecuanitlan's ceremonial mound seems to mimic nearby mountain ridges. As at La Venta, strong north-south directionality created by earthen mounds distinguishes sacred space from the day-to-day world. Furthermore, similar cosmological imagery is found in comparable contexts at all three sites.

Chalcatzingo and Teopantecuanitlan introduce non-Olmec elements, though. At Teopantecuanitlan, monolithic sculptures are found aboveground, apparently replacing the La Venta buried offerings. Teopantecuanitlan and Chalcatzingo both utilize sunken plazas as a way of defining ceremonial space, a technique not found among the Olmec. Finally, residential spaces are more closely associated with the ceremonial precincts; in fact, the two may be combined at Teopantecuanitlan.

The early concept of the Olmec heartland as the origin of a mother culture that spread throughout Mesoamerica is now largely outmoded. Olmec characteristics are evident in non-Olmec areas far from the Gulf Coast heartland, though, as evidenced by the central Mexican sites of Chalcatzingo and Teopantecuanitlan.

THE MOTHER CULTURE–SISTER CULTURE DEBATE

Originally, similarities between the Olmec type-site of La Venta and non-Olmec sites such as Teopantecuanitlan and Chalcatzingo led to the Mother Culture hypothesis that culture spread from the Olmec heartland through military incursions or colonization. Alternatively, the Sister Culture argument suggested that Olmec and contemporaneous non-Olmec cultures developed independently, not as the result of one-way dissemination. Currently, all three sites are known to have had complex and enduring trade-based relationships. Each site provided goods not available at either of the other two sites, resulting in commercial interaction among the three as well as dramatic visual similarities.

Kaminaljuyu

Kaminaljuyu, a Maya site in the Guatemalan highlands (under present-day Guatemala City), was first populated around 1000 BCE and not fully abandoned until around 800 CE. Most known for its initial development, early Kaminaljuyu (Maya for "Hill of the Dead") exhibits many of the elements—the erection of monuments, massive architectural precincts, and written records—associated with later lowland Maya civilization (ca. 200–900 CE) farther to the north and east in Belize, the Petén region of Guatemala and Mexico's Yucatan Peninsula. In fact, Kaminaljuyu is one of the first examples of major site development in the region and evidences an effort, on a monumental scale, connected with urban lifestyles and the needs of large populations to adapt to the surrounding environment.

Situated on the shores of the now nonexistent Lake Miraflores, with its fertile agricultural conditions, Kaminaljuyu controlled trade routes connecting the highlands with the Pacific coastal,

➤ KAMINALJUYU STELE 11

(Gianni Dagli Orti/Corbis)

Kaminaljuyu Stele 11 presents the clear image of a ruler wearing a bird mask and standing between two incense burners. Such imagery was probably meant to justify the lord's position as ruler through his ability to communicate with the supernatural realm. Many of the steles from early Kaminaljuyu incorporate hieroglyphic texts in a language close to, if not the same as, that found in the lowlands to the north. Stele 11 lacks such a lengthy inscription, but it does seem to include an early form of the *ajaw* ("lord" or "king") glyph on the ruler's skirt.

—Maline Werness

Caribbean, and lowland regions by the period 1000–400 BCE. Major building programs were undertaken, and other modifications to the site included an extensive water management system. Steles—tall freestanding stone monuments—also began appearing. Architectural platforms were another innovation, oriented to the cardinal directions and designed for public display. Some

structures were decorated with large stucco masks, a typical development found farther north in the lowlands. The growing complexity of architectural features, the control of trade routes, and the erection of monuments all seem to indicate the development of a social hierarchy centered on elite control.

By the period 400 BCE–200 CE, Kaminaljuyu had become an extremely powerful chiefdom or state with increasingly hierarchical social structures, as evidenced by the many elaborate and valuable offerings found in elite burials. By the end of the period, Kaminaljuyu is estimated to have had 4,500 people living within the city itself, with an additional 5,700 people living in areas linked to and sustaining the great site. Major building and rebuilding programs were also conducted during the period, and five distinct areas developed, each with discrete clusters of large earthen mounds. These different regions within Kaminaljuyu may have been associated with important lineage seats and the burial of significant individuals. Ancestor veneration was probably practiced at this time, given the evidence of grave reentry. Furthermore, many steles, such as Stele 11, were erected, and writing developed. In fact, all the hieroglyphic inscriptions found at Kaminaljuyu are associated with early steles.

Occupation continued until around 800 CE when the city was abandoned, as were many other Maya centers in the lowlands. Kaminaljuyu was the center of the first Maya state, and its organization and administration paralleled those of lowland Maya centers. In fact, it is possible, even likely, that Kaminaljuyu provided the model for the later kingdoms of the lowland Maya. Despite its importance as an archaeological site in Guatemala, much of Kaminaljuyu has been destroyed by modern development because it lies beneath Guatemala City. Fortunately, early surveys of Kaminaljuyu exist, and the nation is engaged in ongoing and concerted efforts to preserve sections of the site.

Formation of Teotihuacan and the Building of the First Pyramids

The ancient city of Teotihuacan was located in an alluvial valley in the northeastern side of the Valley of Mexico, where the San Juan River and its tributaries drain into Lake Texcoco.

Based on ceramic typology and stratigraphy, archaeologists have delineated six phases for this site, lasting from around 200 BCE to 700 CE. Though its incipient period (phases Cuanalan and Patlachique) is poorly understood, archaeological data shows that the next two centuries (Tzacualli to Miccaotli phases, 1–200 CE) were characterized by monumental construction during which time Teotihuacan quickly became the largest and most populous urban center in the New World, reaching around 200,000 inhabitants.

Archaeologists have interpreted the earliest occupancy of the Teotihuacan Valley as a group of small dispersed farming villages located strategically in an area with rich agricultural potential, close to freshwater springs, and maguey plantations (to extract *pulque* and fibers). The area was also near the Otumba and obsidian deposits as well as clay and basalt sources. For the duration of this formative period, Teotihuacan was still a marginal place compared to Cuiculco, which was one of the largest sites of the Basin of Mexico with unique monumental pyramids.

As a result of the eruption of the Xitle volcano Cuiculco was abandoned, and the consequent demographic rearrangements led to massive migrations to the northern part of the Basin of Mexico. At some point in the phases

Patlachique and Tzacualli, the first urban center in the Teotihuacan Valley was founded in the northwestern sector, far away from previous occupancy and far from the agricultural lands and water resources for irrigation. There are no apparent defensive reasons that explain the election of this area in the valley. However, the existence of several cave entrances in this new area, with strong ritual connotations in Mesoamerica, could explain the new concentration of populations. The urban development of this moment was characterized by three temple plazas surrounded by the dwellings of the inhabitants. Sometime later came the construction of the Pyramids of the Sun and the Moon, and the Street of the Dead was also planned at a later date.

Cultures in the Valley of Mexico—Cuiculco and Teotihuacan

Modern archaeological research in the Basin of Mexico began with stratigraphic tests at the archaeological site of Teotihuacan (located in a valley with the same name in the northeastern basin) by Manuel Gamio in the 1920s and Preclassic village site excavations by George Vailant during 1928–1936. Beginning in the 1960s, meticulous surface reconnaissance and selected site excavations as a part of settlement pattern research became a standard research protocol. Large-scale research began in urban Teotihuacan by Rene Millon and his colleagues and with intensive surveys and excavations in the rural Teotihuacan Valley and then the entire Basin of Mexico by William Sanders and his associates. Instituto Nacional de Antropología e Historia archaeologists conducted important research in Teotihuacan and the Aztec capital, Tenochtitlan-Tlatelolco (Mexico City).

BASIN OF MEXICO RELATIVE CHRONOLOGY

Sidereal Periods Time	Basin of Mexico/ Teotihuacan Valley	Major Archaeological Phases
1520–	Colonial	Colonial Hispanic
1190–1519	Aztec I, II, III, IV	Late Postclassic/Late Horizon
950–1200	Toltec Mazapan	Early Postclassic/Second Intermediate Phase 2

1150–1000	Bomba	Early Preclassic/First Intermediate Phase 2
1300–1150	Manantial	Early Preclassic/Early Horizon Phase 2
1400–1300	Ayotla	Early Preclassic/Early Horizon Phase 1
1500–1400	Coapexco	Early Preclassic/Early Horizon Phase 1
1700–1500	Nevada-Tlalpan	Initial Ceramic
2000–1700		Initial Ceramic
3500–1800 BCE		Archaic
>19,000–2500 BCE		Paleo-Indian

* The terminal date for Classic period Teotihuacan is now disputed; older chronologies indicate circa 750, but reinterpretations favor 650 CE.

—Charles C. Kolb

Paleo-Indian and Archaic period artifacts occurred as scattered stone tools (projectile points and scrapers) used by hunters and gatherers. The earliest habitation with hearths and imported stone tools is at Tlapacoya (19,000 BCE), while the Tequixquiac site produced a carved camelid sacrum (18,000 BCE). Occasionally, artifacts are found in context with Pleistocene/Early Holocene megafauna such as mammoth bones with projectile points at Santa Isabel Iztapan (9000 BCE). A female skeleton and a mastodon were recovered

at Tepexpan on the shore of Lake Texcoco in the Teotihuacan Valley (11,000 BCE). Megafauna became extinct due to climatic change and human exploitation, and a big-game hunting tradition changed to desert adaptations during a dryer era when smaller fauna and a variety of flora were exploited by family groups and small bands (20–25 persons) using smaller projectile points, scrapers, and grinding tools to process wild seeds. During the Archaic, bands migrated seasonally to exploit food resources; the Chalco complex provides evi-

dence for the graduate domestication of maize and other cultigens in Puebla's Tehuacan Valley (4200 BCE), Tamaulipas, and more recently the Basin of Mexico. Ceramic vessels were fabricated to store and cook foodstuffs; bands gradually became sedentary, occupying caves and constructing small settlements.

The fertile basin provided an ideal climate, soils, growing season, and sufficient water to grow maize, beans, squash, amaranth, sunflower, and other cultigens. Farming communities developed and expanded in size, occupying new areas, and spring-fed irrigation systems allowed greater productivity, leading to demographic expansion accompanied by craft specialization and socioeconomic diversity. Ceramics, stone tools, sculpture, and painting evolved, and ceramics and architectural styles became the primary sources for dating sites. Political specialists emerged in Early Preclassic tribal and incipient chiefdom-level communities, and there was competition for local resources that led to the cooperative construction of irrigation works and farmlands and the need to secure territory and resources. Intercommunity cooperation against other groups of villages may have fostered the development of military forces. Nucleated settlements were clustered in the northern and central parts of the basin, but the maximum demographic intensity was in the southeast, such as Coapexco, of 988 acres (400 hectares) and 1,000 inhabitants. By 1000 BCE, 90 percent of the basin's population was concentrated in the south.

The farming village of Cuicuilco (Middle through Terminal Preclassic, 1000 BCE–150 CE) arose as the first monumental civic-ceremonial urban polity in the southwestern basin, occupying 370 acres (150 hectares) with a population of 7,500 during the Middle Preclassic and expanding to 988 acres (400 hectares) with 20,000 inhabitants by 150 CE. The city had pyramids—one truncated seeped conical pyramid (400–200 BCE) was 65 feet (20 meters) high and 360 feet (110 meters) in diameter—and other public architecture but was apparently abandoned following the eruption of a nearby volcano, Xitle, in 150–200 CE due to ash fall and lava flow. The flow from this eruption covered 30 square miles (80 square kilometers) to a depth of 32 feet (10 meters), and the flow is today known as Pedregal

➤ BASIN OF MEXICO

The Basin of Mexico lies near the southern end of the Mexican Meseta Central, a broad upland located in the Mexican Neovolcanic belt composed predominantly of Quaternary volcanic extrusives with additional Tertiary solidified magma in the north, while the southern sections have Mesozoic sediments and Paleozoic-Cenozoic metasediments and extrusives. Geologically, it is an internally draining hydrographic unit located on a highland plateau at an average elevation of 7,349 feet (2,240 meters) above mean sea level and encompasses an area approximately 43 miles (70 kilometers) east-west and 74 miles (120 kilometers) north-south (approximately 3,088 square miles, or 8,000 square kilometers) surrounded by mountains and volcanoes (some still active). Although located in the tropics, because of its elevation the climate is temperate. Five interconnected lakes (Texcoco, Chalco, Xochimilco, Zumpango, and Xaltocan) covered most of the basin floor until the past century. Today, these lakes are drained, and the terrain is altered significantly. The area is nearly coterminous with the Distrito Federal and the eastern half of the Estado de Mexico; Greater Mexico City covers about 65 percent of the basin. Humans have inhabited the basin for 20,000 years, and in the Prehispanic era it was the center of several civilizations: Teotihuacan (Classic, ca. 150–650 CE) and Aztec (Late Postclassic, 1190–1519) with Early Postclassic Toltec (ca. 950–1150) immigration from north of the basin.

—Charles C. Kolb

de San Angel. In 2000, volcanologists reported a new set of radiocarbon dates for a Xitle eruption: 245–315 CE. It is unclear if this documents a second eruption or if the other dates are in error. The lava field preserved the ancient settlement but makes conventional archaeological methods difficult, as has the twentieth-century sprawl of Mexico City (therefore, settlement size and demographics should be regarded with caution). Another basin volcano, Popocatepetl, erupted during the first century CE and affected areas to the southeast (the Tetimpa Puebla site was abandoned) and likely impacted Cuicuilco. Other eruptions occurred during 3195–2830 BCE and in 800 BCE, 215 BCE, 675 CE, and 1095 CE.

Cuicuilco-Ticomán culture was defined on the basis of excavations by George Vaillant in Preclassic villages in the western basin at the type sites of Zacatenco, Ticomán, and El Arbolillo. Sites reached up to 247 acres (100 hectares), and architecture and elaborate grave goods facilitated the creation of relative chronologies based on ceramics and clay figurines. During the Terminal Preclassic (200 BCE–200 CE), two regional centers buffered from one another were comparable in population (approximately 20,000 persons each): Cuicuilco (988 acres, or 400 hectares) in the southwest and Teotihuacán (1,482 acres, or 600 hectares) in the northwest basin; the latter was situated around natural springs in the middle Teotihuacán Valley. Although there were small heterogeneous farming settlements scattered in the eastern basin's Texcoco Plain (and likely to the west and north), the Cuicuilco and Teotihuacán were competitive polities.

Marked regional resettlement with a major demographic increase at Teotihuacán resulted from Cuicuilco's abandonment and migrations; whether peaceful or forceful is not known. Within a century, Teotihuacán's population more than doubled, and vast city planning initiated an urban grid system, the construction of monumental architecture (square-based pyramids, temples, palaces, elite and commoner residences), a trade system based on the control of obsidian resources, and unique art styles and ceramics. A state-level society and eventual empire would emerge. By 450 the urban zone was 9.5 square miles (24.5 square kilometers) with 125,000–200,000 inhabitants.

Oaxaca Valley and Early Monte Alban

Like the Basin of Mexico, the Valley of Oaxaca was the scene of major coordinated regional archaeological efforts by Mexican and American scholars. Beginning in the 1940s, Alfonso Caso, Ignacio Bernal, and Jorge Acosta were pioneers of Oaxacan research and were followed by American archaeologists John Paddock, Kent Flannery, Joyce Marcus, Richard Blanton, Robert Drennan, Steve Kowalewski, Gary Feinman, and Linda Nicholas, among others. Settlement pattern research in Oaxaca beginning in the late 1960s was an outgrowth of Basin of Mexico research.

Paleo-Indian artifacts are less common in comparison to the Basin of Mexico but occur at Late Pleistocene Cueva Blanca (near Mitla, Oaxaca) and the early Naquitz phases. Guilá Naquitz (Río Salado Valley) was a small Archaic period cave encampment at 6,318 feet (1,926 meters) elevation and 984 feet (300 meters) above the valley floor with eight occupation levels and was inhabited by small bands (5–15 persons) during circa 8000–6400 BCE that foraged for wild plants, collected and hunted fauna, and gradually shifted from food procurement to the incipient farming of beans, squash, and maize, which sustained larger populations (25–40 persons). They made chipped and ground stone tools from local resources, created cordage and basketry, and were similar to contemporaries living in the Tehuacán Valley to the northwest between Oaxaca and the Basin of Mexico. Gheo-Shih and Cueva Blanca (winter and summer macroband hunting campsites, respectively) had a variety of projectile point types that provide documentation for the Jícaras and Blanca phases, while the Martínez Rockshelter, 1,968 feet (600 meters) from Guilá Naquitz, was a final stage of the local Preceramic.

The establishment of sedentary village life was a critical change in the development of civi-

➤ VALLEY OF OAXACA RELATIVE CHRONOLOGY

The chronology of the Valley of Oaxaca is complex, with gaps and regional variations. A conflated version, largely depending upon settlement and ceramic studies, linguistic analyses (glottochronology), and radiocarbon dating, appears below.

Sidereal Periods	Valley of Oaxaca	Major Archaeological Phases
Time		
1521-	Colonial	
1100–1520	Monte Alban V	Late Postclassic
750–1000	Monte Alban IV	Early Postclassic
500–750	Monte Alban IIIB	Late Classic
300–500	Monte Alban IIIA	Early Classic
100 BCE–300 CE	Monte Alban II	Proto-Classic
300–200	Monte Alban Late I or IB	Late Formative
500–300	Monte Alban Early I or IA	Late Formative
700–500	Rosario Phase	Middle Formative
850–700	Guadalupe Phase	Middle Formative
1150–850	San José Phase	Early Formative
1500–1150	Tierras Largas Phase	Early Formative
1800–1500	Espiridión Complex/Phase	Initial Formative
+/- 2000	Martínez Phase	Preceramic
3300–2800	Blanca Phase	Preceramic
5000–4000	Jícaras Phase	Archaic
8900–4800	Naquitz Phase	Paleo-Indian to Archaic
>11,000 BCE	Early Ajuereado Phase	Paleo-Indian

—Charles C. Kolb

lization in the Valley of Oaxaca, leading to tribal and incipient chiefdom societal types. The site of San José Mogote in the northern Etla arm yielded the remains of a wattle-and-daub house and the earliest pottery (bowl and jar forms derived from gourds) thus far discovered from the Valley of Oaxaca (Espiridión phase, ca. 1900–1400 BCE). The subsequent Tierras Largas phase, named for a site in the Central Valley northeast of Monte Alban, saw a proliferation of tribal-level village sites along the Atoyac and Salado rivers and a dramatic increase in ceramic vessel shapes and decorations and clay figurines related to the growing of maize and teosinte. Village architecture included elite and nonelite do-

mestic habitations and public ritual structures. Rapid demographic growth and regional organizational differences occurred in the various arms of the valley. Each arm formed a coherent region separated by a buffer zone, or no-man's-land. The San José phase was characterized by a ceramic complex with Gulf Coast Olmec ceramic motifs and shell and is similar to artifacts from Tlatilco in the Basin of Mexico (1150–850 BCE). By 850–700 BCE there were 45 communities and a total of 2,000–2,500 persons of different statuses in the valley.

By the Rosario phase (700–500 BCE) the valley had 3,400 inhabitants, while the San José site, covering 173 acres (70 hectares) and with

➤ VALLEY OF OAXACA

The Valley of Oaxaca, a Y-shaped geological basin covering approximately 965 square miles (2,500 square kilometers), is located in Mexico's rugged southern highlands and has a basal complex of Precambrian gneisses and schists, Mesozoic limestones, and Miocene volcanic tuffs. The valley includes the upper drainage basin of the southward-flowing Atoyac River (the northern or Etna arm of the valley) and its tributary, Rio Salado (flowing east to west through the eastern or Tlacolula arm) conjoining in the Valle Grande (Central Valley). The Atoyac then flows south through the southern or Ocotlán region and then west outside of the basin to join Rio Verde, emptying into the Pacific Ocean. Four smaller valleys (Ejutla, Sola, Miahuatán, and Chichicapan) join or lie near the valley on the south. The Central Valley has an average elevation of 5,085 feet, or 1,550 meters (range 4,658–5,708 feet, or 1,420–1,740 meters), and the valleys are surrounded by mountains that rise to 9,842 feet (3,000 meters) above sea level. Three topographic zones—alluvium and piedmont (together approximately 617 square miles (1,600 square kilometers) and mountains—provide diverse resources. The climate is semiarid, and like the Basin of Mexico, moisture is critical for farming. The Oaxaca Valley was a location of early Mesoamerican plant domestication, the evolution of early writing, and the locus of Mesoamerica's first city, Monte Alban, that remained one of its larger settlements 500 BCE–700 CE and the archaeological precursor to the ethnohistoric Zapotec and Mixtec civilizations.

—Charles C. Kolb

1,000 persons, represented the final stage of an early chiefdom period in the valley. Direct evidence for social conflict and raiding was seen in a purposefully burned temple and other dwellings and in the bas-relief depiction of a slain or sacrificed male captive at San José. The first glyphic writing in Mesoamerica dates to 600 BCE at this site. The Rosario phase immediately preceded the founding of a new political capital, Monte Alban, an urban center situated on a mountaintop in the buffer zone in the center of the three-armed valley that would dominate the valley for a millennium. New data indicated that

it was not until 20 BCE that Monte Alban overcame its main rival, San Martín Tilcajete, a chiefdom located in the southern arm of the valley. Other evidence documents an in situ development of the center formation rather than formation by migrants from the Olmec Gulf Coast or Mixteca Alta suggested by John Paddock. By 400 BCE, Monte Alban had 5,200 inhabitants, approximately half of the region's total population, with another 5,000 living in more than 260 villages of fewer than 100 inhabitants.

Within 300 years (Late I) the bulk of the population was aggregated at Monte Alban, and its population exceeded 17,000. It exhibited other characteristics of an incipient state-level society, notably a densely settled community with a heterogeneous population, social stratification, and economic and craft specializations. There were three distinct barrios (neighborhoods) in Monte Alban Early I likely housing migrants from the separate regions of the Valley of Oaxaca. Although the monumental architecture of this civic-ceremonial center associated with the Main Plaza, measuring 984 by 656 feet (300 by 200 meters), dates to later periods and much of the Early I construction was obliterated by later building, the plaza itself was a large open space on an artificially leveled ridge and was planned early in the city's history. Arrowhead-shaped Building J dates to the Late Preclassic. Dating initially to Early I were 320 *danzante* (dancer) nearly life-size bas-relief portrait sculptures—so-called because of their contorted postures—that represent tortured or sacrificial victims (lifeless positions and genital mutilation) or clinical surgical cases (childbirth and deforming illnesses). The true nature of these depictions is unknown, but the numbers of reliefs increased during Late I. A larger and more complex political administration, standardization in ceramic manufacture, and the construction of hundreds of artificial terraces for housing and dozens of architectural clusters covering the ridge and flanks of the mountain characterize Late I. By Monte Alban II defensive walls were completed, and the capital's population had decreased slightly to 15,000, while the valley's demographics increased to 40,000 and military outposts were established outside of the valley. The evidence for statehood is unmistakable, and

Monte Alban's political power grew and expanded into a regional polity that was encompassed by military conquest, cooption, and colonization of external areas, Cañada de Cuicatlán to the north and the Ejutla and Sola de Vega valleys to the south.

The Early Civilizations of Peru

The west coast of South America is dominated by the Andes mountain range, home of some of the world's highest mountains. The central Andes comprise two parallel ranges known as the Cordillera Negra or Occidental in the west and the Cordillera Blanca or Oriental in the east. The Andean environment, although rich and varied, is an exceptionally difficult one for human survival. The elevation changes drastically over short distances, water is often scarce, and climatic fluctuations cause frequent droughts. Andean society was profoundly affected by this challenging environment and was in many ways uniquely adapted to it.

Despite the fact that only about 2 percent of the land area is suitable for agriculture, this region became one of the world's great centers of civilization. Prior to the rise of the Incas, a multi-

tude of cultures flourished and died out in ancient Peru, each one adding its unique contributions to the Andean cultural legacy inherited by the Incas. Only a few of these are well known and have been studied by archaeologists.

The earliest widespread cultural influence is manifested in the style associated with the religious cult of Chavín. By 1400 BCE, this new religious movement had begun to spread across northern Peru. It incorporated elements from older Peruvian coastal religions and combined them with religious elements such as the caiman and jaguar from the tropical forests of the *montaña* and Amazon basin.

Although named for the site of Chavín de Huántar, a ceremonial center and temple complex on the eastern watershed of the north-central highlands, the cult seems to have originated throughout a broad area of northern Peru and represents a synthesis of a variety of traditional religious beliefs. By 1300–1200 BCE, temples and artworks associated with this cult had been built in the northern highlands and on the northern coast of Peru. By 1000 BCE, the influence of Chavín had appeared as far south as the area near where the modern city of Lima now stands. The cult continued to expand, and by 500 BCE, Chavín influence had extended from the modern cities of Cajamarca in the north to Ayacucho in the south. The local culture in the Inca heartland at this time is called Marcavalle by archaeologists, named for the site where its remains were first discovered near the city of Cuzco. Very little is known about these people. They seem to have been farmers who probably occupied a number of villages and lived under a relatively simple political system. In terms of material culture, the Marcavalle peoples seem to be related to those of the Lake Titicaca basin to the south.

In the southern Andes, in what is today Bolivia, a large ceremonial center developed on the shores of Lake Titicaca. This magnificent city, called Tiwanaku, was built at an elevation of 12,630 feet (3,850 meters) above sea level on the cold, treeless plateau called the altiplano. The exact dimensions of the city are not yet known, but preliminary studies indicate an urban center of nearly 1.54 square miles (4 square kilometers). Although Tiwanaku is above the tree line,

the altiplano produces abundant grass, making it prime grazing land for alpacas and llamas. Some high-altitude crops such as potatoes, *ocas* (a sweet potato-like tuber), and quinoa (a grain high in protein) could also be grown. The cold waters of Lake Titicaca, the world's highest navigable freshwater lake, also provided resources such as fish and waterfowl.

Although this severe environment seems hostile, in prehistoric times this area supported one of the densest population concentrations in the ancient New World. Population estimates for the city of Tiwanaku and its sustaining area range between 570,000 and 1,111,500 people.

First settled around 1000 BCE, the site of Tiwanaku was occupied for nearly 2,000 years. It began as a small farming village, but around 100 CE the people began to construct monumental architecture, and the site grew to be the capital city of an empire that dominated the southern Andes between 500 and 1000 CE.

The other great culture of the Middle Horizon (540 CE–900 CE) that originated before the Common Era is that of the Wari. About 600 miles (965 kilometers) to the north of Tiwanaku, the Wari capital was located in the Ayacucho Valley of the central Peruvian Andes, at an elevation of 9,000 feet (2,743 meters). The Wari empire is represented archaeologically by large architectural complexes found throughout the Peruvian highlands. Wari and Tiwanaku shared some of the same religious iconography, but they seem to have been separate entities. There is no evidence that one ever dominated the other, although the exact nature of their relationship remains unknown. The only place where Wari and Tiwanaku archaeological remains are found together is on the site of Cerro Baúl in the Moquegua Valley on the south coast of Peru, where there is some evidence of a violent confrontation.

The site of Wari was first occupied around 200 BCE. Like Tiwanaku, it was only a small settlement until around 500 CE. A new religion is presumed to have been introduced to the Wari through contact with Tiwanaku, but little is understood about this religion. As with most agricultural societies, the Wari religion was undoubtedly concerned with ensuring fertility and a water supply and protecting against natural disasters such as drought or flood.

Religious iconography suggests that there were several deities in a ranked hierarchy, some with several aspects. Most prominent and presumably most important was the staff god or front face deity derived from the Chavín staff god. This deity is often shown grasping staffs that take the form of serpents, which are associated in Andean cosmology with lightning and rain. It is also sometimes depicted as either male or female, grasping various plants in place of the staff, perhaps indicating a connection with fertility and agriculture. Another motif is a figure shown with a knife and severed human heads who is interpreted as the “sacrificer.” Human sacrifice seems to have been practiced. Offering caches have been discovered containing the bodies of sacrificed young women and ritually broken, elaborately painted pottery. Other caches contain high-status goods including objects of gold, bronze, and shell as well as human skulls. Two temples have been excavated at Wari, but the rituals that took place within them are not yet understood to any great extent.

Chavín de Huántar in the Andes

Chavín de Huántar has long been considered one of the most influential places in the Andean region. The site never became a true urban center, but the temple there figured prominently in the development of Andean ideas and cosmology. People's beliefs and practices from both the coast and the Amazon basin influenced the specific iconography and ideology propagated by the adherents of the Chavín religion, and the Chavín style became one of the most widely distributed in the Andean region. Because of this, the Chavín has been compared to the Olmec of Central America as a kind of mother culture for many later traditions. New suites of carbon dates, however, place final construction phases ending before 500 BCE, suggesting that Chavín rose and fell alongside many Andean religious centers.

Chavín de Huántar is located at the confluence of two rivers, the Huachecsa and the Mosna, near the Callejon de Huaylas in the northern highlands of present-day Peru. The Mosna is a tributary to the Marañón and thus indirectly to the Amazon. The location puts Chavín de Huántar equidistant from the Pacific Coast and the lower slopes of the Andes on the edge of the Amazon basin in terms of walking distance. This placed Chavín de Huántar ideally on the landscape to serve as a center for exchange of coastal and Amazonian goods and ideas. The junction of the rivers lies at 10,334 feet (3,150 meters) above sea level, where it receives ample rain averaging more than 33 inches (850 millimeters) per year, a climate well suited to a combination of camelid herding and an agriculture based in high-altitude crops such as potatoes and quinoa.

Three or four factors figured prominently in Chavín's economic success. First, long-distance trade across many ecological zones facilitated by Chavín's location contributed significantly to the economy. Second, irrigation agriculturalists working on the valley floor interacted and exchanged products with highland animal husbandry experts specializing in the meat and wool of llamas and alpacas. A third factor in the economy may have been technological innovations developed by local people in the areas of metallurgy and textile production. Innovations included combined

wool and cotton textiles, tapestry techniques, dyed wool, annealed gold and silver, and the production of three-dimensional forms. Finally, at an early date tribute or offerings brought to the temple of a religious cult centered at Chavín also contributed significantly to the community's success. The importance of these factors changed over time at Chavín as the temple grew, flourished, and eventually failed.

Archaeological discussions of Chavín de Huántar have long been based on artistic and ceramic chronologies. John Rowe defined four artistic styles of stone carving without specific reference to absolute dates. Style AB, represented by the Lanzon, cult image, and carvings in the circular plaza, are placed earliest in the sequence. The famous cayman image on the Tello Obelisk defined Style C. Archaeologists associated all three early styles with the construction of the northern section of the architectural monument known as the Old Temple and with Urubarriu ceramics dated as early as 1200 BCE. Rowe used the Black and White Portal to define Style D and the Raimondi Stone to define Style EF. These late styles became associated with construction of the southern portion of the monument referred to as the New Temple or Castillo and with ceramics classified as Chakinani and Janabarriu. New analysis of the major architectural components suggests that Chakinani and Janabarriu ceramics date to an occupation phase after major construction ceased around 500 BCE. Carbon dates still support the continued use of the site through about 200 BCE as proposed by archaeologists Richard Burger and Luis Lumbreras.

Work in the 1990s and the early twenty-first century conducted by research teams from Stanford University used sophisticated mapping techniques and computer-aided design to reanalyze the architectural sequence of the temple monument. Based on increasing standardization in the construction of internal passageways, or galleries, and the superposition of architectural volumes, archaeologists can now discern 15 construction phases. Earliest construction at the temple created separate platform mounds with internal gallery spaces. One of these, at the heart of what has been called the Old Temple, housed and provided access to the Lanzon, an anthropomorphic image with both feline and serpentine attributes carved

THE DIFFERENCE A DATE MAKES

The ability of archaeologists to date materials and the cultures that produced them has improved dramatically over the last 100–150 years with the introduction of seriation techniques, stratigraphic excavations, and an array of radiometric and nonradiometric dating technology. We can now add to this suite of improvements advanced computer mapping techniques that allow archaeologists to better understand the spatial and temporal relationships between archaeological remains. In many cases archaeologists expected that improved dating would provide subtle refinements in our understanding of early history. In the case of Chavín de Huántar, however, new understandings of construction sequences require us to think about the site and its place in prehistory in entirely new ways. Where Chavín was once seen as a late synthesizer of Early Intermediate period religious traditions and the innovator behind the Early Horizon, it now appears that Chavín was only one of many cult centers of the time and that the major expansion of ideas came after the temple system collapsed.

With so much change in archaeological conceptions of Chavín, it is interesting to note what seems to be relatively stable: our understanding of Chavín religion. Of course, revised chronology of the temple's construction does impact how we think the religion was organized and how it interacted with its adherents. The basic understanding of Chavín's central ideas and practices, however, have remained fairly constant: ideas centered on a series of animal images, ideas of shamanic transformation, the power of water, and a balance of complementary elements. Why have these con-

cepts remained when so much else has changed? Largely this appears to be due to the differences in the kinds of data used to support our hypotheses. While so much of archaeology relies on temporal and spatial patterning, our understanding of religion has come from interpreting the images in Chavín art, and though patterns have changed, our ability to see and interpret birds, cats, cactus, and other images has remained the same.

Focus on 3 chronological phases of development is based on radiocarbon dates, stratigraphy, and stylistic seriation of materials. New research on the construction of the major architectural features suggests as many as 15 separate phases. The Urabarriu phase (1000–500 BCE) saw the initial settlement of two distinct residential sectors: canalization of part of the Huachecsa River and construction of the first large religious structure, the Old Temple. The site saw social, economic, and geographical reorganization during the Chakinani phase (500–400 BCE). These changes included a shift to a single contiguous settlement on either side of the Huachecsa River, construction of the New Temple, and an economic shift toward specialized craft production and away from self-sufficiency. It is not until the Janabarrui phase (400–200 BCE) that the site reached its population peak of 2,000–3,000 people and exhibited signs of social differentiation and what has been called proto-urbanism. After 200 BCE, however, construction and repair of the major buildings ceased. In time, people with Huarás pottery occupy the site, building homes in ceremonial plazas and robbing stone from the temple walls for construction material.

—Jo Ellen Burkholder

on a large granite prism. This image remained a major focus of cult activity throughout the site's construction and use. As the power and authority of temple leadership grew, construction raised the height of the buildings, added internal passageways, and eventually consolidated the platforms into a single large stone-faced building by about 750 BCE. As suggested by earlier chronologies, the final phases of construction realigned the central axis of the complex with the Black and White Portal and the Monumental Stairway, considered part of the New Temple.

Changes in later construction focused on expanding and altering access to ritual. This included the construction of plazas with elaborate decoration. These added large amounts of formally defined public space. The last construction phases also covered patios associated with the internal galleries. Combined, these changes suggest a dramatic shift from individual and small group rituals to those involving the participation of hundreds of people or more. This shift in architectural style represents conscious attempts of the temple leadership to ma-

nipulate its growing constituency of religious adherents.

Based on thematic content of the art of Chavín, the religion focused on what were to become prominent and repeated images and ideas in Andean cosmology. One aspect was the importance of water, particularly moving or flowing water. Marine mollusks—strombus and spondylus—may have represented the ocean, while the cayman deity of the Tello Obelisk recalled the waters of the Amazon basin. The temple itself was located at the confluence of two rivers, and hydraulic features inside of the Old and New Temples might have been flushed with water to make the building reverberate, or roar. Other repeated animal images include raptorial birds, snakes, and felines, all of which may relate to the other hypothesized aspect of the Chavín religion, shamanic transformation. Sculptures such as the tenoned heads illustrate metaphysical aspects of transformation from human to feline, avian, or other animal form. Inhalatory drug paraphernalia with Chavín-style images and depictions of San Pedro, a mescaline-bearing cactus, suggest that hallucinogenic drugs played an important role.

The ideas and images from Chavín became popular and widespread in association with Janabarrui-style ceramics after 400 BCE. Early interpretations questioned whether new popularity necessitated the expansion of the temple or an expanding temple provided the base for extending religious and economic influence. New understanding of construction sequences would now place the expansion of Chavín, or Chavín-like iconography, in the period after the temple had fallen into disrepair and its sacred precincts were inhabited by people not associated with the temple's operation. Images created by or in imitation of Chavín artists were distributed from the Lambayeque Valley on Peru's northern coast to as far south as Karwa on the southern coast where cotton textiles with male and female versions of the Lanzon/Raimondi stone deity came to light. While many credit the power of the Chavín ideology for the wide distribution of the iconography, some suggest that the technological advances in metallurgy and textile production associated with Chavín drove the demand for Chavín products.

The Nazca and Moche Cultures

The Early Intermediate period (200 BCE–600 CE) of western South America witnessed the development of two different complex social-political systems. On the northern coast of Peru isolated clusters of settlements coalesced into the Southern Moche state, incorporating territory from Chicama to the Huarney Valley and centered in the Moche Valley and a northern polity or polities encompassing the Piura, Lambayeque, Zana, and Jequetepeque valleys. In southern Peru inhabitants of the Rio Grande de Nazca Valley and perhaps the Ica Valley developed signs of social and political complexity but probably never developed into a full-fledged state. During the early development of the south the site of Cahuachi on the Nazca River acted as a major pilgrimage and religious center but was never a densely populated urban site. Both the Moche and Nazca cultures developed distinctive artistic traditions with complex iconography associated with pervasive religious beliefs.

Nazca culture (100 BCE–1000 CE) emerged first in the Rio Grande de Nazca drainage, which encompasses several small and sometimes intermittent tributaries: the Grande, Palpa, Ingenio, and Nazca are the most significant. The presence of early versions of Nazca pottery in the neighboring Ica Valley to the north suggests very early expansion or cultural continuity with

ART AND LIFE

The art of Nazca and Moche is noted for its realism, but does it represent real life and how can we tell? In the case of the Nazca and Moche fact is as strange as fiction, and myth and reality were not that far apart.

For decades archaeologists studying Moche thought that they could tell the difference between mythical narratives and portrayals of the mundane world. But there might be more to Moche myth than meets the eye. Elite tombs excavated in the 1990s contained individuals buried with the costumes of people depicted in the Presentation Theme and the Burial Theme, scenes once thought to be purely mythical. Excavations near the Huaca de la Luna also located the remains of sacrificial victims like those in Moche myth. Thus for the Moche, myth was sometimes reality. On the other hand, some now suggest that scenes showing human warriors, fishermen, medical conditions, various sexual acts, and even images of food stuffs represent elements of complex mythical narratives, not scenes from real life.

What then do we make of Nazca art? Nazca art also depicts both natural and supernatural themes. In addition to identifiable images of the natural world, Nazca artists rendered a seemingly endless variety of anthropomorphic creatures sporting rayed projections, animal-like appendages, fanged mouths, and long tongues and carrying severed human heads. But we have clear evidence that the Nazca actually collected human heads. Discoveries of elaborate masks, once thought the property of lords, now suggest that some Nazca may have donned costumes of supernatural beings to reenact sacred stories, as did the Moche. At the same time, the fact that realistic renderings of animals in Nazca pottery mimic geoglyphs created

Double spout and bridge pottery vessel with a bird deity, Nazca culture, Peru, 200 BCE–600 CE. This globular jar depicts a fantastic bird in flight with a human face, adorned with a mouth mask and a diadem. The bird holds a human trophy head. (British Museum/Art Resource, NY)

as part of Nazca religion suggests that the smaller images may reflect spiritual belief, not just the natural world. Like the Moche, the Nazca may have lived in a world where supernatural and natural worlds were not separate places.

—Jo Ellen Burkholder

that area. While the Nazca people are famous today for the construction of the Nazca Lines, identity of Nazca people appears to have been more closely tied to artistic and iconographic traditions and the construction of specific types of civic-ceremonial complexes.

The site of Cahuachi is the largest of the Nazca civic-ceremonial complexes. It had a small residential population, and excavations at the site suggest the presence of textile specialists

there. There has been no evidence so far of specialized pottery production, although its existence has been posited. In addition to the small residential community, Cahuachi was predominantly a place of pilgrimage and ceremony, not an urban center. Some corporate religious structures exist, but many of the complexes of flat-topped pyramids, modified natural hills, plazas, and cemeteries were probably created and maintained by corporate kinship groups. Construc-

tion using *chala*—cornhusks either singly or in bundles—is a unique feature of the artificial construction. Pilgrimage at Cahuachi peaked between 200 and 400 CE and was likely related to the use or creation of many of the well-known geoglyphs in the neighboring pampa. Nazca culture became increasingly secular after the Middle Nazca period (450–550 CE). This corresponds with the decline in importance of Cahuachi as a pilgrimage center and with development of filtration gallery irrigation systems in the southern part of the Nazca drainage.

Nazca residential sites tended to be small, especially in the Rio Grande de Nazca drainage. Sites occupied gentle slopes and artificial terraces. Construction materials for houses were largely ephemeral, although some sites made use of more durable naturally occurring materials. Size of sites does not seem to be related to architectural differentiation, nor is it a predictor of intrasite status differentiation. Cemeteries occupied areas in and adjacent to residential areas as well as discrete locations with tomb types highly variable across time and space.

Nazca people produced a distinctive style of representation seen in both ceramic and textile art. From it we can recognize specific examples of plants and animals and many human activities. These representations included comestible plants, flowers, cactus, birds, fish, monkeys, and camelids as well as men and women both clothed and naked. In addition to portrayal of the real world, Nazca artists paid special attention to a supernatural world rich in anthropomorphic creatures that harvested plants and human heads, wore elaborate costumes, and sprouted rays, streamers, feathers, and other projections.

The northern valleys of the Peruvian coast from Piura to Huarmey witnessed the development of the first centralized state and urban centers with the development of the Moche culture (100–900 CE). Moche political centralization drew upon a common cultural base of economic reliance on agriculture and aquatic resources, spiritual beliefs, and probably patterns of kinship and political organization. People in adjacent northern valleys shared these traits despite being known today by their different pottery styles: Salinar, Gallinazo, Moche, and Vicus. Emergent leaders used common cultural ties,

their control of food surpluses and luxury goods, and a developing religious and political ideology to gain control. The shared cultural base was a remnant of the pervasive Chavín culture of the previous millennium, while a growing system of irrigation canals allowed for the production and manipulation of food surpluses. The ideological component appears to have been a new invention of the increasingly powerful elite, although it was likely based on extant myths and practices of the northern coast.

Scholars have begun to debate the specific nature of Moche political organization. One point of agreement in this debate is that the extensive area in which Moche material culture is found never experienced a unified political system. There is also considerable consensus that the southern valleys from Chicama to Huarmey were unified as a polity, with a political and social capital on the Moche River. Debate continues as to whether the northern sphere from the Jequetepeque Valley north ever saw a cohesive political system emerge and what characterized the relationship between the Southern Moche state and the northern polity.

The most impressive Moche center was probably Cerro Blanco (also known as Moche), which served as the capital of the southern state. Cerro Blanco, like other Moche centers, was dominated by large platform mounds, or *huacas*, of molded adobe bricks. The Huaca del Sol and Huaca de la Luna at Cerro Blanco are among the largest adobe constructions in South America. Workers built mounds in stages, creating multiple conjoined segments and marking their labor with distinctively incised bricks. Some huacas were sites of deity worship and human sacrifice, while others served as places for elite burial. Although the Huaca del Sol was almost completely destroyed in colonial times, extravagant burials from the site of Sipan hint at the wealth and power of the elite interred in these artificial mountains.

Between and around the huacas were residential areas where Moches lived behind high adobe walls in extended-family compounds. These compounds functioned as residential, social, and economically productive spaces. Specialized workshops led by master craftspeople developed in these compounds under elite

patronage. Some produced finely crafted gold, silver, and copper objects alone or inlaid with shells and semiprecious stones. Others produced fine pottery either using molds or modeling clay by hand. Ceramic artists depicted people wearing a wide variety of decorated garments, suggesting that textile specialists also plied their craft in specialized compounds. Regardless of the media, however, Moche artists, like those of Nazca, focused most if not all of their attention on depictions of a mythical world filled with demons, warrior deities, and bloody rituals.

■ Introduction: Religion and Environment

Scholars used to believe that ancient religions (especially mythology) were simply elaborate attempts to make sense of the natural world. While this is now understood to be a gross oversimplification (ancient religions were complex and sophisticated systems of thought, just as modern religious traditions are), it is clear that ancient religious perspectives did inform people about the natural world. Likewise, the natural world informed ancient people about religion and spirituality. Mesoamerican pyramids, for example, were thought to be symbolic of cosmic mountains and reflected the initial creation of the world. For the Greeks, the natural world was the location of chaotic and dangerous elements as well as life-giving forces. For readers of the Hebrew Bible, the natural world was something granted by God for human stewardship. This topic seeks to explore some of the ways in which religion and environment informed one another in the period from 1000 BCE to 300 CE.

—Kevin M. McGeough

Hebrew Bible and the Natural World

In recent years, a number of writers have argued that the Bible is environmentally unfriendly in that it urges mankind to exploit the natural world.

Most such accusations point to God's words to the newly created humans in Genesis 1:28:

“and God said to them, ‘Be fruitful and multiply, and fill the earth, and subdue it; and rule over the fish of the sea and over the birds of the sky and over every living thing that moves on the earth.’”

It should be noted that the Hebrew word translated as “subdue” does not necessarily entail destruction; indeed, the Israelites “subdue” the Promised Land when they enter it, but they certainly do not destroy it. Clearly, though, the message of this passage is that humanity is given mastery over the world. This position appears to contrast sharply with that of the nonmonotheistic religions, in which humans are part of the natural world rather than somehow above it.

But what form is this mastery to take, exploitation or stewardship? The biblical laws do express concern about the overcultivation of land (e.g., the fallow laws of Exodus 23:10–11 and Leviticus 25:2–5) and overworking domesticated animals (who, like humans, are covered by the Sabbath commandment). In addition, a survey of poetic passages with naturalistic themes suggests that the biblical authors were not as environmentally insensitive as is sometimes alleged. Psalm 104, for example, highlights God's concern for nature (see especially vv. 10–18), while

God's answer to Job (Job 38–41) is a tour de force of naturalistic imagery, extolling the wonder and beauty of the natural world. These and other examples suggest that while the Hebrew Bible cannot be said to be as green as, say, Native American faiths, it does reflect, both in law and poetry, an appreciation and concern for nature.

Ancient Near Eastern Flood Myths

The book of Genesis contains an account of a catastrophic flood that wiped out all of humanity except one righteous man, Noah, and his family (6:5–9:17). According to the biblical story, God regrets having created man because humanity has become corrupt. In order to destroy mankind, God releases a flood upon the earth. Before sending the flood, God warns Noah to build an ark and to board it with his family and with a variety of animals. After the floodwaters recede and upon descending from the ark, Noah offers a sacrifice to God. When God smells the pleasing odor of the sacrifice He promises to never wipe out man again with a flood. God sends a rainbow as a sign of this promise, and humanity is reborn from Noah's seed.

The Genesis flood story contains both inconsistencies as well as redundancies. For example, in one verse God commands Noah to bring one pair of every kind of animal upon the ark (6:20), and later He instructs Noah to bring seven pairs of every clean animal and one pair of every unclean animal (7:2–3). The account also contains redundant and stylistically diverse descriptions of God's decision to send the flood (6:5–6 and 6:11–13). Most scholars attribute these features to a blending of two different versions of the same flood tradition.

THE HEBREW BIBLE (RSV) ON ENVIRONMENTAL RESPONSIBILITY

Exodus 23:10–11: "For six years you shall sow your land and gather in its yield; but the seventh year you shall let it rest and lie fallow, that the poor of your people may eat; and what they leave the wild beasts may eat. You shall do likewise with your vineyard, and with your olive orchard."

Deuteronomy 20:19: "When you besiege a city for a long time, making war against it in order to take it, you shall not destroy its trees by wielding an axe against them; for you may eat of them, but you shall not cut them down. Are the trees in the field men that they should be besieged by you?"

God the Naturalist, Isaiah 41:19–20: "I (God) will put in the wilderness the cedar, the acacia, the myrtle, and the olive; I will set in the desert the cypress, the plane and the pine together; that men may see and know, may consider and understand together, that the hand of the LORD has done this, the Holy One of Israel has created it."

—John Walton Burnight

A similar flood account is recorded by Berossus, a third-century Babylonian historian. Although Berossus's history is only preserved in citations by later Greek scholars, among these quotations is an account of a calamitous flood. The passages refer to a flood that destroyed everyone except for Xisuthros, the tenth king of the Babylonians. Warned by the god Cronus, Xisuthros builds a boat and survives.

For many years the Bible's account and excerpted quotes from Berossus were the only two ancient Near Eastern flood stories known to scholars. Beginning in the 1850s, however, a slew of new material began to emerge. In 1851 an archaeologist who was excavating the mound of Kuyunjik, under which lay the ancient city of Nineveh, hit upon the library of the Assyrian king Ashurbanipal. Among the many clay tablets found in Ashurbanipal's chamber was a Babylonian flood account. This seventh-century flood story is part of a larger epic about a king named Gilgamesh who, after witnessing the death of his friend, engages in a pursuit for immortality. On the eleventh tablet of the 12-tablet narrative, Utnapishtim, someone who has achieved

ACCOUNTS OF THE FLOOD

When translating cuneiform texts into English, scholars use square brackets [] to denote parts of the inscription that are missing but have been reconstructed by the translator and parentheses () to indicate words that are not in the original text but have been supplied to make the translation more understandable.

Bible (NRSV)	Gilgamesh	Atrahasis
In the six hundredth year of Noah's life, in the second month, on the seventeenth day of the month, on that day all the fountains of the great deep burst forth, and the windows of the heavens were opened: And the rain fell upon the earth forty days and forty nights: On the very same day Noah. . . entered the ark. . . and the Lord shut him in: The flood continued forty days upon the earth and the waters increased and bore upon the ark and it rose high above the earth. . . . And the waters prevailed so mightily upon the earth that all the high mountains under the whole heaven were covered . . . all flesh died that moved upon the earth, birds, cattle, beasts, all swarming creatures that swarm upon the earth and every man: Everything on dry land in whose nostrils was the breath of life died.	In the evening the leader of the sto[rm] caused a destructive rain to rain down. I viewed the appearance of the weather. The weather was frightful to behold. I entered the ship and closed my door. . . . A black cloud came up from out the horizon. Adad thunders within it. . . . Like a battle [it ca]me over the p[eo]ple. No man could see his fellow. The people could not be recognized from heaven. (Even) the gods were terror stricken at the deluge. They fled (and) ascended to the heaven of Anu. The gods cowered like dogs (and) crouched in distress. Ishtar cried out like a woman in travail. The lovely-voiced Lady of the g[ods] lamented. . . . The Anunnaki wept with her. When the seventh day arrived the tempest, <i>the flood</i> which had fought like an army, subsided in (its) onslaught. The sea grew quiet, the storm abated, the flood ceased . . . and all mankind had turned to clay.	After he had bolted the door Adad was roaring in the clouds. The winds became savage as he arose . . . the flood. . . . Its might came upon the peoples [like a battle array]. One person did [not] see another. They were [not] recognizable in the destruction. [The flood] bellowed like a bull. . . . The darkness [was dense] there was no sun. [Enki] was beside himself. . . . Nintu the great lady, Her lips were covered with feverishness. The Anunnaki, the great gods, were sitting in thirst and hunger. The goddess saw it as she wept. For seven days and seven nights came the deluge, the storm, [the flood].

immortality, tells Gilgamesh about a time when the gods wiped out humanity with a flood. Warned by the god Ea, Utnapishtim builds a boat and brings his family, friends, animals, and possessions inside it until the rains cease and the floodwaters recede. Utnapishtim descends and offers a sacrifice to the gods. Subsequently the god Enlil blesses Utnapishtim with immortality.

In 1898 a scholar published a seventeenth-century fragment of a Babylonian flood story that differs from Ashurbanipal's Gilgamesh nar-

ative. It took until 1956 for this fragment to be joined with other relevant tablets and for the narrative to be fully understood. This forerunner to the Gilgamesh narrative is referred to by scholars as Atrahasis, after the name of the protagonist. The discovery of Atrahasis reveals that in its earlier incarnations the flood tradition was not connected to a hero's pursuit for immortality. Atrahasis also fills in some gaps in the Gilgamesh story. For example, the Gilgamesh story does not explain why the gods send a flood to

wipe out humanity. Atrahasis explains that Enlil, the god consigned to govern the earth, is unable to sleep because of the noise emanating from the human populace. Therefore, the distraught god decides to reduce the population.

After Enlil's attempts to diminish mankind through a plague and a drought are thwarted by the god Enki, Enlil decides to annihilate man with a flood. In the course of the flood many gods weep. They grieve over the loss of human life and because humans were originally created to provide food for the gods. Luckily for these grieving and hungry gods, Enki again thwarts Enlil by surreptitiously warning Atrahasis to build a boat and with it save himself and his family. When the floodwaters recede Atrahasis alights and offers a sacrifice. The hungry gods "[sniffed] the smell" and crowded around the sacrifice.

The similarities between the Bible, Atrahasis, and Gilgamesh are striking and suggest that all three accounts stem from a common tradition. Nevertheless, the accounts diverge in significant ways. For example, in Atrahasis although the flood rids the world of noise, it is not a permanent solution to Enlil's problem because the gods still need men to work to provide food. As a more workable solution, the gods limit the number of human births. "In addition let there be a third category among peoples . . . women who bear and women who do not bear . . . the Pasittu-demon to snatch the baby from the lap of her who bore it." In the Bible, after the flood God commands Noah's family to procreate: "Be fruitful and multiply, and fill the earth."

The impermanent nature of the flood solution in Atrahasis and the consequent regulation of births can perhaps illuminate the role of the divine laws that follow the biblical flood. After the deluge God promises that he will never again destroy man with a flood because "man is evil from his youth." Instead, God establishes laws proscribing acts such as murder. While the flood provides a temporary antidote to wickedness, perhaps the divine laws are intended to more permanently curb the evil impulses that provoked God to release the flood in the first place.

Since the original discoveries of Gilgamesh and Atrahasis, other versions of these works as well as other works that mention a flood, rang-

ing from the Old Babylonian period through the Late Assyrian period, have emerged. For example, in 1914 a similar flood story was published and, despite its being written in Sumerian (a language spoken in the third millennium), is probably no older than the earliest Atrahasis tablets.

Early Chinese Views of Nature

The peoples who inhabited what we now call China from prehistory through the end of the Han dynasty (202 BCE–220 CE) developed a set of assumptions about the natural world that influenced all subsequent Chinese cultural history as well as neighboring civilizations throughout East Asia. Early Chinese thinkers observed that while the natural world clearly operated according to cyclical patterns and processes, it was not entirely predictable and could inflict great harm on human populations. From this observation emerged the view that the natural and human worlds formed a harmonious, organic, and interdependent whole.

Several environmental factors conditioned early Chinese views of nature. The advent of agriculture (ca. 2000 BCE) made it both possible and necessary to sustain a large human population. The hot summers, freezing winters, and regular floods of the Yellow River valley complicated this task. Early agriculturalism inspired two basic metaphors used by many later thinkers—the flow of water and the growth of plants—as well as the myth of a devastating flood quelled by the heroic sage Yu, founder of the legendary Xia dynasty (ca. 2183–1752 BCE). The earliest known writing in China (ca. 1700 BCE), known as scapulamancy, was inscribed on

View of a River and Mountains from Album of Eight Landscape Paintings by Shen Zhou. This Ming dynasty (1368–1644 CE) painting is typical of earlier Chinese views of nature by locating human figures at the bottom of the picture plane and dwarfing them with much larger landscape features. (Burststein Collection/Corbis)

animal bones, which then were heated in order to divine the answers to questions from rulers, many of which had to do with natural events such as weather. This attests to the confidence of the early Chinese in their ability to understand and even predict natural processes.

While the investigation of nature was not a major concern among early Chinese thinkers, those who did focus on the natural world did so primarily in order to enable human beings to predict and control natural events and processes. Followers of Mozi (ca. 468–376 BCE), now known as Mohists, developed sophisticated theories of geometry and optics primarily for military applications. Astrologer-scribes (*shi*) at royal courts studied the natural world in the hope of deciphering omens and portents. By the late Warring States (403–221 BCE) and early Han eras, the Chinese had developed a comprehensive correlative cosmology. According to texts such as the *Lüshi Chunqiu* (*Spring and Autumns of Mr. Lü*, ca. third century BCE) and thinkers such as Dong Zhongshu (ca. 179–104 BCE), human actions naturally trigger reactions in the nonhuman world and vice versa. For this reason, Chinese rulers from this period onward were advised to conduct their affairs in such a way as to prevent natural disasters and effect natural events that would benefit their subjects.

Nature in Greek Myth and Religion

To the Greeks, the natural world—the world outside the boundaries of the inhabited regions—was the diametric opposite of the civilized world of the city-states. Unlike the city-states, the natural world was perceived as an inherently lawless place of both miracles and monsters. Greek religion and mythology reflect the difference between the natural and the civilized worlds in the character of the gods associated with the natural world and in the myths told of the interactions of men and women with the natural world.

We can recognize three spheres of influence within the Greek world, based on human ability to tame the region: the urban world of the city-states, where laws and customs maintain order; the domesticated world of fields and crops, which could be bent to the will of humans, with the consent of the beneficent Demeter; and the natural world, in particular the mountains and the ocean, which could be exploited but never trusted or controlled.

The natural world provided necessary food, wood, and pastures but was also home to real and metaphorical monsters, such as the Centaurs and Amazons, threats to the civilized world; various uncivilized humans lived in the mountains, where they violated the traditional social order with impunity before finally being destroyed by the Athenian culture-hero Theseus.

The gods associated with the natural world were powerful, hostile, and more apt to harm rather than to help. Poseidon, the god of the sea,

had a changeable and inherently untrustworthy nature, just like the sea. He could have been propitiated with sacrifices before a sea journey and thanked upon its successful completion but never fully trusted. Artemis, the god of animals and wild spaces, was dangerous, unpredictable, and quick to punish mortals who crossed her, even inadvertently. Dionysus, the god of ecstasy and release from social constraints, quickly and happily destroyed those who offended him. The best that one could have hoped for from the gods of the natural world was that they would leave you alone.

The Cosmological Symbolism of Mesoamerican Pyramids

Mortuary pyramids in Mesoamerica have deep symbolic roots. These man-made structures were built by commoner labor over a period of several months. Rotating gangs of laborers toiled to bring in rocks, dirt, plaster, and paints to build and decorate a structure 98 feet (30 meters) on a side and upwards of 32 feet (10 meters) high. This investment, under the direction of the current ruler, honored the deceased ruler with a permanent home for his remains.

There were many kinds of pyramids, and each was identified with particular deities or dedicated for particular uses. Prominent deities included the gods of the sun, moon, stars, wind, water, and lightning, and each required its own sacrifices and distinct ceremonies. In addition to god-houses, pyramids were constructed to mark time's passage, to identify prominent lineages, for ancestor cults, to honor the gods of war, and as astronomical devices.

SEMONIDES ON ENVIRONMENT

Setting aside the issue of misogyny, this text by Semonides clearly exemplifies the Greek mindset toward the sea and reflects its concern with the natural world.

"Then the god made another woman out of the sea, one who has two minds. One day she laughs and is happy. . . . But another day she will not tolerate being looked at or approached. She rages fiercely, just like a dog with puppies, harsh and hateful to both enemies and friends equally. Just so the sea often stands motionless, harmless, a great delight to sailors during the summer, but often rages, bearing loud-thundering waves, so this type of woman is very like the sea in anger. And the sea has a different nature at different times" (translation by author).

—Kelly MacFarlane

Source

Semonides fr. 7.27–42.

Yet symbolically, pyramids were more than buildings. They were living structures with their own spiritual life forces. The first layer of symbolism was that of mountains. Because these structures generally towered above the forest line, they resembled small mountains from the distance. This imagery reminded the viewers of their own creation myths. Once the world was full of water until the gods raised the mountains and separated the heavens. In another legend, the creator gods lived on the summit of a mountain, and creation events began there. Mankind's origins were associated with mountains. Man was created from the bones of a previous creation pulled from the underworld. Thus, dead rulers were interred into a man-made cave under the pyramid awaiting rebirth.

An early Classic Maya version of this symbolism was found at San Bartolo, Guatemala. The north wall of the Piramide de las pinturas, sub-1, showed a mythological scene of creation and rebirth. On the left side of the mural was the cave mouth in the shape of a serpent's mouth, similar to monuments elsewhere in

► FLOWER MOUNTAINS

For Mesoamerican peoples, Mountains of Sustenance, or Flower Mountains, were primordial places of creation. They were uncivilized spaces where wild animals attacked and roamed. Into such savagery, it was believed, the first humans emerged onto the earth. Mesoamerican pyramids evoked that imagery and thus were linked to cosmic ideas of order. Gods and men subdued nature and created civilized space. Pyramids, as significant sacred spaces, then become the axis mundi or pivot of the world for each city and the point of origin for the territory. Each ruler sought to extend his civilized space by increasing the borders around his built sacred mountains.

Pyramid of the Sun and the ruins of the ancient city of Teotihuacan. (Corel)

Mesoamerica. The stalactite formed the fang. On the rear of the serpent's head were scenes of wild animals hunting and devouring one another in a flowery forest setting. Inside the cave, the stretched-out serpent formed the floor upon which the Maize god was being dressed in preparation for his rebirth. Feathers along the serpent identified it as a plumed serpent, important in Mesoamerican legend. This treatment of "Flower Mountain" coincided with Aztec concepts of the "Mountain of Sustenance" from which the sun was born.

■ Introduction: Envisioning the Landscape

The natural world was replicated in a number of ancient artistic media. We have the best evidence for Greek and Roman artistic endeavors along these lines. Poems extol the virtues of nature, and paintings (especially as preserved at Pompeii) celebrate idyllic conceptions of the environment. Greek and Roman gardens, however, are perhaps the most direct attempt to envision the landscape in a controlled setting. While these gardens are preserved only

indirectly, they offer great insight into the aesthetic sensibilities of the ancient Greeks and Romans as well as their conceptions of a more controlled natural landscape.

Gardens and landscape art were not unique to the Greeks and Romans. The Mesopotamians had long had a tradition of depicting the art in sculpted reliefs. And, of course, the Hanging Gardens of Babylon, one of the Seven Wonders of the Ancient World, were celebrated in their

own time as a momentous site to behold. In China, the walls of tombs were decorated with illustrations of the natural world and the cosmos. For the people of Peru, the landscape was depicted on pottery and textiles, and the landscape itself was altered on a monumental scale in the form of what have come to be called the Nazca Lines.

—Kevin M. McGeough

Assyrian and Persian Gardens

Suburbs outside the walls of Mesopotamian cities were set among gardens and fields, and within the city there were often parks. Texts show that wealthy households often had private gardens with grapes, fruit trees, vegetables, and other plants and furnished with pools.

One text describes the shade-tree garden belonging to the eighth-century Babylonian king Marduk-apla-iddina II (Merodach-Baladan), with 67 different kinds of plants divided into 14 groups, possibly the contents of separate beds. Of these, only 26 can confidently be identified, including garlic, onions, leeks, lettuces, cucumbers, radishes, beetroot, turnips, Indian gram, and various herbs and spices, among them at least 5 varieties of mint.

Sennacherib (704–681 BCE) constructed a temple at Assur for the *akitu* festival, during which the god's statue was taken to a garden. Within this temple's courtyard and around its outside were gardens destined for divine courtship according to texts. Excavations have revealed neatly laid-out rows of root pits and the remains of trees or shrubs.

The ancient Mesopotamians required their gardens to provide shade, fruit, and fragrant

THE HANGING GARDENS OF BABYLON

Tradition has it that the most splendid gardens were the Hanging Gardens of Babylon. Classical authors described the gardens as resembling a mountain, with terraces of brick, bitumen on stone foundations, and planted with trees. A hidden mechanism, a remarkable feat of engineering, raised water to the highest terrace, and there were pavilions among the vegetation. They attributed this to Nebuchadnezzar II, although the king's own inscriptions do not mention such a garden.

The gardens' remains have not been located, although it is possible that they lie within an unexcavated area between the river, the North Palace, and the Western outwork. However, many scholars find this unconvincing. It is puzzling that Herodotus, who probably visited Babylon in the fifth century BCE, made no reference to the gardens although he described the city's other impressive features.

Recently, Stephanie Dalley has suggested that the Hanging Gardens of Babylon were actually the gardens of Sennacherib at Nineveh, a misattribution due to Classical confusion about names: Herodotus and later Classical writers often did not distinguish between the Babylonians and the Assyrians, and Nineveh, the Assyrian capital, was known in later times as Old Babylon. Babylonia had no tradition of

creating gardens on artificial hills, while these are well known from Assyria. The description of the Hanging Gardens closely matches what is known of Sennacherib's palace gardens. In particular, Sennacherib describes a device he had made for lifting water to the top of the garden. Although the meaning of the words used for the device's components is uncertain, Dalley shows that they probably describe a bronze cylinder containing bronze spirals, in effect an Archimedes' screw centuries before Archimedes. This matches the description in Classical texts of a hidden mechanism and some explicit references to it as a water screw (though there remains the possibility that this device was introduced into the gardens after Assyrian times). On balance, Dalley's theory seems convincing.

scents; these were places to relax and eat and to enjoy courtship. When Assyrian kings built new capital cities or embellished earlier ones, they considered it important to include parks and gardens within their designs. Royal gardens were constructed on artificial hills, providing topographic variety much appreciated in the generally flat local landscape and recreating the natural pleasures of other lands. Assyrian kings delighted in growing exotic trees and other plants acquired during their conquests or as tribute. Sennacherib planted “trees bearing wool,” the earliest Mesopotamian reference to cotton.

Ashurnasirpal (883–859 BCE) created a garden at his new capital, Kalhu (Nimrud), constructing a canal to supply it with water from the upper Zab River in the Zagros Mountains. He claimed to have planted 41 varieties of trees that he had collected in foreign lands, including cedar, cypress, box, myrtle, oak, fir, willow, ebony, acacia, juniper, almond, date-palm, pistachio, pomegranate, olive, plum, pear, quince, and fig. He repeatedly expressed his pleasure in his scented garden, a place of delight where he often gathered fruit and where “waterfalls glisten like the stars in heaven.”

Sargon II created royal hunting parks and orchards when he founded Dur-Sharrukin (Khorsabad) in 713 BCE. A relief shows an artificial hill clad with pines and full of birds, with an altar on the summit; behind it is another slope with pines and fruit trees, and there is a pillared pavilion before which is a lake with two small boats. Sargon likened his park to Mount Amanus and said that it contained every kind of tree from the Hatti lands (Syria); the pavilion as an architectural feature was also borrowed from this region. A surviving letter to the king from a provincial governor reported that several consignments containing thousands of apple trees, hundreds of medlar trees, and almond, quince, and plum trees were on their way to Dur-Sharrukin.

A relief in the palace of Ashurbanipal (668–627 BCE) shows the gardens that his grandfather Sennacherib created around the vast “Palace without a Rival” in his new capital, Nineveh: they rise up over tree-clad slopes to a terrace with a pillared pavilion, and through them run many streams fed by an aqueduct. Sennacherib took a keen interest in civil and hydraulic engineering. He created an artificial swamp outside Nineveh that was stocked with wild boar, deer, and fish and attracted heron and other birds; the swamp was inspired by the marshlands of southern Babylonia. This acted as a reservoir, absorbing the excess winter flow of water from the canals. The aqueducts, weirs, dams, and tunnels that he constructed to bring water to Nineveh from the mountains, some of which are still in use, watered a huge area of arable land and orchards around the city as well as parks and gardens within it. The most sumptuous was the royal pleasure park beside his palace, which he planted with vines and all kinds of spices, fruit trees, and trees for timber. Cypress and mulberry trees from the garden along with reeds from the artificial marsh were used in Sennacherib’s building works.

Assyrian kings also created hunting parks outside the city walls in which many wild animals were kept for royal sport, vividly pictured in the magnificent reliefs of Ashurbanipal’s palace. In some reliefs the king and his attendants ride after wild asses, or beaters drive gazelle toward the king hidden in ambush. Others include sensitive portraits of Mesopotamian lions

(smaller than African lions and only recently extinct) relaxing in the park among trees, flowers, and vines. In one sequence, lions are transported in cages to the hunting ground, its perimeter surrounded by soldiers and keepers with mastiffs, while eager spectators climb an overlooking hill. As the lions are released, the king pursues them with bow and arrow in his chariot or on foot, protected by a shield bearer, and finishes off a wounded beast with his sword in hand-to-paw combat, grasping the rampant lion by the throat.

A long tradition in Mesopotamia made it both the prerogative and the duty of the king to hunt lions. The earlier king Ashurnasirpal claims to have captured 15 adult lions and 50 lion cubs to provide breeding stock for his park, where he also kept wild bulls, elephants, ostriches, bears, wild asses, deer, panthers, and monkeys.

The Persians also constructed royal gardens (*pairadaeza* or “enclosed space,” whence “paradise”). These shared with Mesopotamian gardens the emphasis on fruit trees and trees providing fragrance; their function as places of recreation, relaxation, and privacy; the incorporation of pavilions; and the provision of hunting parks. However, while Mesopotamian gardens were designed to re-create natural landscape, those of the Persians were laid out in formal geometric arrangements and were planted with trees in lines, luxuriant grass, and other plants. The excavated garden of Cyrus the Great’s capital at Pasargadae filled the areas around and between two open-sided pillared palaces, with porticos and stone benches and two similar but smaller pavilions. The gardens were laid out in formal rectangles beside which ran stone watercourses with deep basins at intervals. A throne in the center of the principal palace portico allowed the king to sit in shaded ease. The rectangular garden in front of this palace was divided into four by water channels: this perhaps symbolized the traditional Four Quarters of the World of which Cyrus was now master.

Persian kings spend much time in their gardens, of which they created examples in the Persian cities of Ecbatana, Pasargadae, Susa, and Persepolis as well as in conquered lands. According to the Greek author Xenophon, the Spartan general Lysander visited the royal garden at Sardis in the company of Cyrus the Younger, who was

delighted by his guest’s appreciation of its beauties since he himself had designed it and had even planted some of the trees with his own hands.

Greek and Roman Gardens

In Greece, the formal garden does not seem to have existed. Natural gardens abound in Greek mythology, from the Gardens of Hesperides to the rose garden of King Midas. But apart from Homeric gardens, only a few sacred groves are mentioned. They are laid out near temples and represent a magic, idealized, and separate place apart from the rest of the natural world.

Shady trees were planted around gymnasia, markets, and meeting places, such as Plato’s Academy and Aristotle’s Lyceum. It was only after Alexander’s conquests in the fourth century BCE, when the Greeks developed a taste for “Persian paradises,” that attractive places began to arise in cities. In book seven of the *Odyssey*, Homer provided a colorful description of Alkinoos’s garden.

By contrast, the Romans loved nature, and vegetation played a major role in their houses. Deeply attached to their homes, they considered gardens to be the most important element in a harmonious life. At first, gardens were designed as real sacred landscapes with pergolas and kiosks, reminiscent of what we find in Hellenistic paintings.

The courtyard (atrium) of a house might be planted with shrubs and succulents. Behind the

THE GETTY VILLA

(Propix)

The Getty Villa Museum in Malibu, California, built in 1970 to display the art collection of J. Paul Getty, houses an array of Greek and Roman antiquities. The main peristyle of the Getty Villa is intended to be a copy of the villa of Papyri at Herculaneum, the owner of which might have been Julius Caesar's father-in-law.

The open spaces of the different peristyles feature pools, bronze sculptures, fountains, benches, and about 300 varieties of plants used by the Romans in cooking, ceremony, and medicine.

—Marie-Luce Muracciole

atrium extended a pleasure garden (peristyle) where more utilitarian plants such as vegetables and fruit trees as well as plants for preparing aromatics and dyestuffs would be found. These gardens consisted of trees, flowers, fishponds, fountains, and carefully selected statues arranged in a complex design. The main rooms opened out to the garden, where summer dining rooms would be located in some cases. Gardens were also used as status displays to show how cultivated a patron might be. Roman gardens were enriched by the introduction of new species gained through conquest of Asia Minor. Lucullus, who led the Roman army to victory over King Tigranes the Great and Mithridates in Armenia, introduced the cherry tree to Rome at the beginning of the first century BCE. In addition, Roman gardeners advanced the pageantry of the formal garden by creating a new technique that consisted of trimming shrubs in geo-

metrical shape or in the shapes of animals. The apogee of this design was reached at Hadrian's Villa in Tivoli (118–138 CE), where gardens were conceived as an “imaginary place.”

When the house was too small to have its own garden or when rooms did not open to the outside, landscapes were painted in *trompe l'oeil* (a painting style with photographically realistic detail) on the walls with trees and flower-covered banks around which birds fluttered. Gardens were intended to serve as a living environment. Many examples from Pompeii or the house of Livia (wife of the emperor Augustus) in Rome illustrate these bright sceneries.

Greek Landscape Painting

Ancient literary sources indicate that the Greek artist Parrhasios wrote a book about painting and that Agatharchos wrote a book on wall painting, while the painter Nikomachos was active in the late fourth century BCE and was admired for his skillful painting. His contemporary, the Greek philosopher Plato, in the fourth century BCE wrote of artists then capable of reproducing earth, mountains, rivers, forests, sky, and all that encompasses them. Unfortunately, only a small percentage of these fragile works of art have survived. Surviving works include Roman wall paintings, but there were probably hundreds if not thousands of freestanding paintings rendered on wood or cloth, designed to hang on walls or rest on shelves. Nearly all of this is lost, particularly any examples of Greek monumental painting.

The earliest images that we can call landscape painting in Western Europe come from the ancient Minoan civilization on the Greek is-

► THE TOMB OF THE DIVER IN PAESTUM

Another important ancient landscape scene that has survived from the Greek Classical period is the fresco from the Tomb of the Diver in Paestum, in southern Italy. The scene shows the astonishing vitality of a young man diving from a stone structure with stylized trees and plants. Painted around 480 BCE, the diving scene is accompanied by banqueting scenes on the four inner walls of the sarcophagus. They are similar to other scenes on Classic vase painting except for the fact that the tomb painter used vivid colors such as blacks, greens, reds, and earth tones. The style is strongly linear, as we find in the vase painting of the era.

—Anton Rajer

land of Crete. The huge palace at Knossos was elaborately decorated with dozens of wall murals that convey a lively impression of the palace life from 2000 BCE. Several of the murals show stylized landscapes with plants in bloom and rocky outcroppings in vivid colors such as ochres, reds, and blacks. Another mural, over 21 feet (6.4 meters) long, is an amazing maritime seascape with playful dolphins, mountains, a port city, and dozens of ships filled with people.

In northern Greece is the tomb of Philip, father of Alexander the Great, dated to around 340 BCE. The walls of the inner chamber are decorated with a long mural over 12 feet (3.5 meters) in length and 3 feet (1 meter) high. The subject is Pluto seizing Persephone. Set in a landscape, the god is in his chariot and clutches the young woman. Painted in a colorful, expressive, and confident manner, the multifigured composition was first drawn in the wet stucco and then rapidly painted, showing that the artist worked free-hand with mastery of the medium. He used warm tones, including violets, yellows, and reds, to convey a dynamic and animated composition. Alas, this is the only mural that has survived from this period in mainland Greece, but it does indicate an advanced and highly developed skill level that may have been widespread. It serves to illustrate an important principle in the ancient arts: that landscape painting was almost always associated with mythological scenes and

did not exist as a separate genre except on rare occasions.

Roman Landscape Painting

Ancient Roman painting had two primary sources, Etruscan and Greek cultures, both of which contributed important styles and techniques that Roman artists found useful in their own work. Roman artists borrowed heavily from these sources but imbued them with their own distinct idiom. Like their predecessors, Roman artists painted mythical and historical subjects but added new genres such as landscape, still life, and architectural illusion. Etruscan tomb paintings, of which there are over 100 extant examples, show a lively interest in the human figure, strong narrative, a mature sense of design, and sophisticated use of color. Because they are located in underground tombs they have survived, protected from the ravages of time. Though the scenes are mostly mythical, some

THE MOSAIC OF THE NILE FROM POMPEII

The mosaic of the Nile from Pompeii deserves discussion. Although made of thousands of small color pieces, the mosaic is the work of a gifted artist familiar with both painted images and mosaic decoration. Conceived of on a grand scale, the Nile mosaic of Palestrina is a virtual tour of the river and the many monuments that dot its shores in Egypt. Made of thousands of pieces of colored stone and glass, the mosaic conveys in graphic form the flooded Egyptian landscape. It is probably a Roman copy of a Hellenistic original from a workshop in Alexandria and was made as a floor decoration for the religious sanctuary of Fortuna at Praeneste, Italy, around the first century BCE. Greek names identify the many animals found throughout, such as crocodiles and hippopotamuses. Nile boats, huts, temples, and figures enliven this fantastic scene that includes plant and water life. The artist used the bend of the river as a device to convey perspective and recession into space as well as to give views of buildings from different angles. These multiple perspectives convey the wonder and monumental quality of the Nile life. This is the grandest landscape image from antiquity and

Detail from the mosaic at Palestrina shows the Nile River delta during flood season. (Sandro Vannini/Corbis)

demonstrates the ability of ancient artists to create landscape images.

Although only a limited number of landscape paintings have survived from antiquity, the few that we have demonstrate a clear interest on the part of ancient artists to portray the natural world around them, filtered through their eyes and time.

—Anton Rajer

show banquets, industry, battles, and portraits and even allude to idyllic landscapes, mostly composed of stylized trees and plants but based upon, at least in part, observed nature. As Rome had already conquered Etruria by 290 BCE, Roman artists would have been aware of these artistic developments. In fact, it is likely that Etruscan artists worked in Rome or contributed to artistic developments in the fast-growing city.

An example survives from an upper-class house from the late republican period, around 30 BCE, that illustrates the influence of Greek art on Rome. The house, located near the Farnesina and the Tiber River, has a number of wall paintings, essentially depicting small imitation pictures in the early classic Greek style of art. Painted on a white ground, the linear composition of human figures is reminiscent of Greek vase painting, done in water-based paints called tempera. The other remarkable thing about this work is that it is signed in Greek “Seleukos made it,” implying

the artist responsible for the artwork but also possibly the adjoining stucco work. In another area of the house is a series of maritime scenes with sea battles sketched in a light and rapid but confident manner; the murals clearly indicate a proficient artist capable of portraying a sense of perspective and three-dimensional illusion.

The most extraordinary example of the highly developed style of Roman landscape painting comes to us from the Villa of Livia, the wife of Augustus Caesar. Located on the Via Flamminia north of Rome, the “garden room” is a painting without parallel, conceived of on a monumental scale: a virtual environment, an entire room, floor to ceiling. Between several low fences rises a dense forest of trees, botanically correct, with lush details including oleander, cypress, laurel, and pomegranates. Birds animate the scenes, often against open blue sky, conveying a realistic effect. This stunning example indicates Roman interest in nature not as mere decoration but as

exact in its rendering. The murals today are located in the Palazzo Massimo in Rome along with several dozen other Roman frescoes preserved in a safe museum environment.

Another extraordinary example is the series of mythological murals found in a house on the Esquiline hill in Rome and today located at the Vatican Museums. The theme is the Odyssey and the life of Ulysses as he wanders from one country to another. The murals are signed with an inscription in Greek, though they may be copies done by a Roman artist around 50 BCE copying a Hellenistic original from about 150 BCE. The paintings have a strong narrative and are painted in an impressionistic, sketchy quality, with the small figures of Ulysses and his men painted in swift, confident strokes. The artist used a coloristic device to convey the sense of perspective and recession into space by using pale colors for the distance, like the optical effect of a hazy distance and atmosphere.

Most ancient wall paintings fall within two painting techniques: true fresco executed on wet plaster or tempera on dry plaster. Both techniques employ essentially the same pigments, mostly earth pigments, such as raw sienna or burnt umber. The Roman architect Vitruvius mentions that some colors, because of their high cost and rarity, such as ultramarine blue, were bought directly by the patron and given to the artist for his work. Furthermore, Vitruvius mentions that fresco requires at least seven layers of plaster, each one progressively finer up to the finish coat, in which the wet pigments were applied.

Housed at the Metropolitan Museum of Art in New York are a group of ancient Roman landscape paintings from the archaeological site of the villa of Boscotrecase, near Pompeii. Painted in about 10 BCE, several mythological scenes tell the story of the Cyclops Polyphemus. He is seated in a large illusionary landscape with his goats, and the sea nymph Galatea is on a dolphin. Another mural depicts the gods Perseus and Andromeda. The works are painted in vivid greens with rock outcropping and a sense of recession into space. The murals, taken as a whole along with others in the room, show a high level of development and sophistication in the mural arts at this imperial Roman villa.

Representations of the World and Cosmos in Chinese Tomb Decor

Tomb construction in China dates to its Neolithic period (10,000–2000 BCE) and continues today. But it underwent significant changes between the end of the Zhou period (1027 BCE–256 CE) and the Han dynasties (206 BCE–220 CE). These material changes represent the shifting ways in which the Chinese understood their relationships to both world and cosmos.

Early evidence of Chinese tomb decor surfaces in the form of funerary urns made of pottery and unearthed from sites located in central China that date to the end of China's Neolithic period. During the Xia (2000–1500 BCE), Shang (1500–1050 BCE), and Zhou periods, use of sacrificial bronze becomes prominent in the artwork found within underground tombs, although pottery vessels are still present. In addition to the finding of sacrificed humans and animals, excavations from some of these early tombs have also revealed items made from bronze, jade, stone, and pottery. Many objects found in these ancient tombs were designed as items through which the dead could continue sacrificing to the higher powers after death.

In the middle and late Eastern Zhou period (770–256 BCE), an important change occurred in Chinese tombs. Made primarily of wood or clay, small figurines representative of humans and other living beings are present. These objects do not signify sacrifice but instead represent companions used to accompany the dead into the afterlife. In the case of the figurines used in the north of China during the Warring States period (475–221 BCE), most were made of

Figure of a charioteer, Eastern Zhou, Warring States period, fourth–third century BCE. (The Metropolitan Museum of Art/Art Resource, NY)

clay and measured no more than 2.5 to 4 inches (7 to 10 centimeters) tall, most likely viewed metaphorically as part of a posthumous cosmos.

These small grave figurines served as models for those found in the later tomb of the famous First Emperor, Qin Shi Huangdi (259–210 BCE), who united China during the Qin period (221–206 BCE). However, Qin Shi Huangdi's enormous tomb complex, found at Lintong, a city near the present-day city of Xi'an in Shaanxi province, comprises multiple halls that spread across acres of land and contains thousands of life-size terracotta figures of warriors and horses. Unlike the miniature figurines found in the tombs of his predecessors, the figures accompanying Qin Shi Huangdi's tomb measure between 70 and 75 inches (180 and 190 centimeters) in height and are collectively called the terra-cotta army. The scale of Qin Shi Huangdi's tomb represents the emperor's envisioning of an actual army, as opposed to a metaphorical one, that would serve and protect him posthumously.

During the early Han period, the use of smaller grave figurines became prevalent again. In one such tomb, the Mawangdui tomb located in Changsha in Hunan province, small wooden figurines accompany the body of a female Han aristocrat named Lady Dai (ca. 168 BCE). Thousands of objects including figurines, documents, and clothes were also found at Mawangdui after the tomb's discovery in 1972. Of extreme intrigue, however, is the painted silk banner found to have covered the coffin containing the woman's preserved corpse. Painted in six pigments, the large banner depicts four cosmological levels: one for the heavens, located at the banner's top and including symbols and images of sun, moon, immortals, and dragons; two for the earthly realms and including a depiction of Lady Dai as an old woman; and one for the underworld, which is located at the banner's bottom.

Archaeological and iconographical studies continue to examine the intriguing religious and metaphysical significations of tombs such as Mawangdui and that of Qin Shi Huangdi.

Nazca Art

Three of the greatest artistic traditions of South America, those of the Moche, the Nazca, and the Paracas cultures, are remarkable not only for the fine quality of the details in the artwork but also for the combination of realism and recognizable icons with mythical and supernatural elements. Though each tradition took a very different approach, all three are also notable for their treat-

➤ MANY TYPES OF ENVIRONMENTAL ART

Non-portable artistic expression has a long history dating back more than 35,000 years, but South America may be unique. Like many regions it has a tradition of rock art going back almost as long as human habitation, but the peoples of South America created art in their environments in a wide variety of forms for a wide variety of purposes. Painting, carving, and geoglyphs represent three basic categories.

The UNESCO World Heritage site in Patagonia, Cueva de las Manos represents the work of some of the earliest settlers in the Americas 13,000 to 9,500 years ago. At this site early Patagonians painted animals from their environment in mineral pigments and signed their work with hand prints leaving a permanent record on cave walls. People continued painting rock surfaces through the Colonial and republican periods including modern graffiti.

Later people also created engraved images known as petroglyphs. The famous Toro Muerto site near Arequipa is only one of hundreds of petroglyph sites in the desert environments around

the colonial city of Arequipa dating from the first millennium BCE through the second millennium CE. These images include animals as seen in the earliest rock art but add anthropomorphic figures and also include strange mythical animals such as two-headed serpents. This suggests that rock art began to represent the supernatural landscape as well as the natural one. Today many rock art sites in the Andes still are regarded as special, supernatural places. Sites with postcolonial uses often have crosses superimposed over ancient glyphs.

Finally, the Nazca were far from the last people in the Andes to create giant artwork from the desert pavement. In the Atacama Desert of Chile people created giant geometric, zoomorphic, and anthropomorphic geoglyphs in a manner similar to the Nazca Lines to mark routes and destinations for camelid caravans particularly after 800 CE. The art possessed an economic or managerial function that transcended representation of the supernatural or natural world.

—Jo Ellen Burkholder

ment of landscape: the Moche for their setting of scenes from mythical narratives in recognizable locations, the Nazca for their monumental treatment of landscape, and the Paracas for their detailed characters that seem to float in infinite and boundless space.

People of the Paracas culture from the Ica region of southern Peru (750 BCE–100 CE) were perhaps the best producers of textiles in the Andean region. By comparison their pottery, though well formed and decorated with incision and postfire paint, is unimpressive. Due to the dryness of the environment along Peru's southern coast and the Paracas Peninsula in particular, natural mummies were preserved in large underground tombs. It is from these tombs, both excavated and looted, that specialists have recovered these textiles.

Paracas weavers were some of the first to combine cotton and camelid wool, creating a variety of fabric types as fine as several hundred threads per inch. These they then embellished with elaborate embroidery and needlework borders. In most of the elaborate embroidery, myth-

ical anthropomorphic figures appear to float in a featureless sea. Head position sometimes appears to suggest flying or swimming, but the terrain is not given any firm indication: no mountains, seas, or plains. We have some sense of what Paracas people valued in their environments from their needlework borders, such as the one on the famous Brooklyn Museum textile that depicts a profusion of animals, plants, and anthropomorphic figures.

People of the Nazca culture (300 BCE–800 CE) also inhabited the dry coastal plains of southern Peru. Overlapping in time and space with the Paracas people to the north, the Nazca were clearly influenced by Paracas ideals, though they developed their own unique styles of textiles and ceramics. One of the aesthetics that Nazca artisans appear to have adopted from the Paracas people is the tendency for the plants, animals, and anthropomorphic figures to float in featureless space. Exceptions to this tendency notably include images of people engaged in fighting and carrying out rituals at flat-topped pyramids.

In addition to more ordinary art forms, the Nazca are also renowned for the construction of large geoglyphs known as the Nazca Lines. Nazca people created a diversity of shapes in the desert pavement. The most noted configuration lay between the Nazca and Ingenio valleys, but glyphs of the same sort can be found in many valleys of the Nazca Drainage. People created the earliest glyphs through an additive technique, piling up rocks from the desert floor. Later, people used a subtractive technique, clearing stones away to reveal the pale earth beneath the dark desert stone. Forms include spirals, zig-zags, straight lines, polygons, and representational figures recalling the animals and plants seen in Nazca pottery and textiles. Based on this association and discovery of pottery fragments associated with the lines themselves, the majority of the geoglyphs can be confidently dated to the Nazca culture and perhaps a little earlier.

The animal and plant figures have captured the most attention. Some suggest that the biomorphic figures were emblematic of clans or representative of supernatural beings and/or constellations. Others have suggested association with specific geological features, natural aquifers, and artificial irrigation systems. In the end the exact purpose for which the Nazca constructed and used the glyphs remains unknown despite the many hypotheses put forth. One point of consensus among scientists, however, is that the Nazca created these many forms to serve a combination of social and religious purposes that likely changed over time.

The Moche people of the Peruvian north coast (100–800 CE) gave rise to the concept of a master craftsman period in Andean prehistory and were easily the most sophisticated ceramic artisans in South America. They created pottery in specialized workshops, producing mold-made and hand-built pieces that they finished with smooth polished surfaces, polychrome slip paint, and complex fine-line drawings. Unlike the art produced in the southern traditions of Paracas and Nazca, Moche art presents a well-developed sense of space and landscape whether rendered in two or three dimensions.

Famous for the realism in human portraiture, Moche artists rendered images of landscape with equal superiority. They manufactured

hand-built pieces in the form of long-necked bottles that depicted the built environment of roofed buildings and flat-topped pyramids as well as three-dimensional representations of rituals taking place among steep mountain peaks. It is in the stylistic conventions of the fine-line drawings, however, that Moche artists achieved the most complex renderings of landscape.

Fine-line drawings reproduced mythical Moche scenes in dark slip paint on a white or creamy ground. Artists created depth of field by one of two methods. First, like some traditions in East Asia they created horizontally arranged panels, the uppermost panel representing the most distant part of the scene. Second, they rendered more distant figures in a smaller scale above the larger foreground figures. Though the scenes, like those of monsters and warriors doing battle, were surely mythical, artists provided a good sense of location by including conventional representations of the environment in which a scene took place. Wavy lines stood for irregular terrain of mountain foothills, volutes represented ocean waves, and tall vertical lines conveyed a sense of marshes of grasslands.

Lesser-known groups of the same period as the Paracas, Nazca, and Moche also represented and used landscape in their art. For example, the Nazca were not the only group to create geoglyphs. Peruvian archaeologists led by Ruth Shady have identified a large geoglyph associated with the site of Caral dated between 1600 and 200 BCE. In the south, archaeologists have identified both large geoglyphs and small rock art panels around Arequipa, Peru, such as at the site of Toro Muerto in the Majes Valley. The style of representation at many sites is consistent with art of the local Sihuas and La Ramada cultures, rough contemporaries of the Nazca. The bounty of environmental art in the south documented up through the Inca and early colonial periods suggests that the tradition of creating enduring and visible art may have changed functions but did not die out with the Nazca.

Society and Culture

The ancient monuments most closely associated with the Olmecs of Mexico are symbols of leadership. Immensely skilled sculptors, the Olmecs have left behind at least 17 colossal stone heads at four different sites. Varying significantly in size and quality, these heads probably depicted ancient Olmec leaders. Each head wears a type of protective headgear, possibly the helmets of ancient ball players. The basalt from which these heads were carved was transported a considerable distance and probably at great expense. These heads undoubtedly held important social meaning for the Olmecs. As with all societies, values change over time, and the respect that ancient Mexicans held for these heads was no different. Now, these statues bear pock marks from ancient vandals, signs of mutilation. Although it is not clear when the mutilation took place, the fact that the sculpting of statues came to an end almost 3,000 years ago attests to the ever-dynamic nature of culture.

From 1000 BCE to 300 CE, Mesoamerican cultures underwent elaborate changes. During this time Olmec civilization vanished, the city of Teotihuacan became a thriving urban center, and the first stirrings of Maya culture can be discerned. Noteworthy about all of these Mesoamerican cultures is the primacy of the city. People began living together in close proximity in large centers. While cities had long existed, it was in this period that urban life became predominant in ancient Mexico. Most extreme was Teotihuacan where, according to one estimate, 200,000 people lived, making up 90 percent of that culture's population. For the Maya even the layout of the city was meaningful, and their cities were laid out in a manner that reflected their understanding of the cosmic order of the world. Beyond Mexico, the city was central to many of the cultures that inhabited the world during this era. For the Greeks, the city (which they called the polis) was the fundamental organizing principle and the largest recognizable polity, although these cities did band together as leagues. For the Romans, the city of Rome was the center of a vast empire stretching all around the Mediterranean Sea. Major cities were present throughout the world from 1000 BCE to 300 CE; Meroe in Nubia, Aksum in Ethiopia, Persepolis in Persia, and the well-planned cities of Zhou China are just a few of the many examples of important urban centers. However, the vast majority of the world's

While cities had long existed, it was in this period that urban life became predominant in ancient Mexico. Most extreme was Teotihuacan where, according to one estimate, 200,000 people lived, making up 90 percent of that culture's population.

population lived outside of cities, and the produce of rural areas was absolutely essential.

These urban centers of the period came to be centers of culture and art, with some of the most important artistic achievements of the human heritage having been conceived and executed during this time. For students of European art, the works of the Greeks and Romans have been especially formative in terms of the development of techniques, skill at naturalistic depiction, and choice of subject matter. Myron's fifth-century *Discobulos* and the bronze charioteer of Delphi, both considered masterpieces of world art, were sculpted during this time. The friezes of ancient Persepolis blended Mesopotamian and Greek artistic aesthetics. Art outside of the western canon is just as noteworthy. Jadeite monuments from Mexico are as striking today as they were 3,000 years ago. The terra-cotta warriors buried along with Qin Shi Huangdi, (d. 210 BCE), the first emperor of China, are remarkable for their individual detail as well as the striking scale of their manufacture. Celtic designs (especially as preserved in ancient jewelry) are still utilized in modern craftworks. Scythian depictions of animals in gold and bronze are exquisite examples of art that was created in nonurban settings.

Architecturally, this period has many marvels. Greek classical temples are instantly recognizable to modern visitors, and much of the architectural sensibility that was established by the Greeks was perpetuated in later European design. Roman architecture was vast in scale and technical sophistication. Roman monuments can be found today in any of the regions of their former empire. Roman cities such as Jerash in Jordan remain nearly intact partially due to the monumentality of their construction. Many of the dark-gray marble monumental buildings of the Persian city of Persepolis still stand today. The first emperor of China, Qin, constructed a massive wall along China's northern frontier, little of which survives today, having been replaced by what is now called the Great Wall of China in the Ming dynasty.

There is a significant amount of architecture from the period 1000 BCE to 300 CE that was devoted to entertainment. In many ways, this period can be seen as the period in which formal entertainment on a large scale was truly born. For the Mesoamericans, public ball courts, designed at the end of the preceding era and the beginning of this era, were utilized for the next 3,000 years. Greek theaters, shaped in a semi-circle, were the settings of the earliest plays. It is in Greece that the dramatic arts first appeared as a formal art, and many of the plays written by Greek authors are still performed today. Musical performances and orations also took place in these theaters, providing the basis for modern concerts and literary readings. Although the architecture of ancient Chinese musical performance is not preserved, its importance is well attested, and *The Classic of Poetry* preserves the lyrics of a number of ancient folk songs. Roman amphitheaters (oval in shape), where gladiatorial combat and other spectacles took place, provide the model for many of today's sports arenas. Roman amphitheaters, like our own arenas, were laid out according to class, with the best seats located closer to the event and the cheap seats being available at the very top of the stadium (the equivalent to modern box seats were available for dignitaries).

Inhabitants of the ancient Indian city of Nagarjunakonda could play board games on boards carved onto slabs covering riverside steps.

The social stratification that was so characteristic of the preceding era continued into the period from 1000 BCE to 300 CE, and if anything, this stratification became more institutionalized. In Greece, the concept of citizenship provided some individuals with the rights of free citizens but explicitly excluded women and foreigners from civic life. In Rome, clothing marked the social status of an individual in a way that was immediately recognizable to everyone. In India, the caste system that had originated in the preceding era rigidly fixed a person's social standing based on birth, preventing social mobility; this system continued to evolve down into the Gupta Age. Slavery was common throughout much of the world from 1000 BCE to 300 CE.

A remarkable feature of the world cultures of this period is the extent to which people still derive their identities from these ancient cultures. This is the period that gave birth to the Greeks (in the sense that we think of them today), the Romans, the Celts, the Han dynasty of China, the Persians, the Maya, and the first Indian empires in South Asia. Rightly or wrongly, many people today feel a direct cultural continuity with the societies of this ancient era.

—Kevin M. McGeough

■ Introduction: The Family

Without a doubt, the family is the fundamental social unit of human relationships. The daily life of most ancient people would have been spent in close proximity to individuals deemed family. The biological reality of human reproduction was usually the basis of family life, but the actual structure of a family—who was considered family and which relationships were most meaningful—varied considerably from culture to culture and from period to period.

There was great continuity in family structure in many regions of the world during the period from 1000 BCE to 300 CE. Family life in the Near East (Egypt, Mesopotamia, and the Levant) remained relatively stable from the periods prior to this.

Family structure in the Greek world became rigidly formalized at this time. Members of a Greek family had carefully prescribed roles and responsibilities within the family, and these roles carried the weight of law behind them. Roman

family structures were similar to that of the Greeks, but the ideal roles were not as rigidly prescribed. This is most apparent in the alternative ideals of family that develop out of Christianity in Roman times. An increasing formalization of family roles can be seen in India and China at this time. Vedic traditions in India and Confucian traditions in China facilitated the development of formal models of family relationships, many of which still inform people's notions of family today.

—Kevin M. McGeough

The Greek Family

The Greek family revolved around the household (*oikos*). The *oikos* encompassed not only the nuclear family (husband, wife, and children, both natural and adoptive) but also members of the extended family (particularly unmarried females and orphaned children) and slaves as well as household property, including animals.

Greek funerary stele depicting a family group, fourth century BCE. (Jupiterimages)

It was also the fundamental economic unit of ancient Greece, not least because inheritance passed linearly from one *oikos* to the succeeding generation.

The Greek conception of the family was both patriarchal and hierarchical. As Aristotle notes (*Politics* 1.1253b), there were three relationships within the *oikos*: master and slave, husband and wife, father and child. The dominant person in each of these relationships was the senior male member of the family, who served as the head of the household (*kyrios*). The *kyrios* not only had final say over household matters (although in actual practice this was probably often done through consultation) but also presided over any transactions (whether business or personal) with the community beyond the *oikos*.

An inheritance was usually divided among male offspring upon the death or retirement of their father. Men in this period customarily established their own *oikoi* by marrying, usually in their early to mid-thirties. Female offspring received their portion of the inheritance in the form of a dowry, which they took with them to their new *oikos* when they married, typically at a much younger age than their brothers. Upon marriage, a woman became part of a new *oikos*, with either her husband or one of her husband's senior male relatives serving as her *kyrios*. She would return to her original household only in the case of divorce or widowhood. When there were no surviving sons, the inheritance was left to daughters, who were then married off to the nearest male

➤ EUPHILETUS

Euphiletus, the speaker in a speech written by the orator Lysias, indicates the ideal family relationship he enjoyed with his wife before she began an adulterous affair:

When I, Athenians, decided to marry, and brought a wife into my house, for some time I was disposed neither to vex her nor to leave her too free to do just as she pleased; I kept a watch on her as far as possible, with such observation of her as was reasonable. But when a child was born to me, thenceforward I began to trust her, and placed all

my affairs in her hands, presuming that we were now in perfect intimacy. It was true that in the early days, Athenians, she was the most excellent of wives; she was a clever, frugal housekeeper, and kept everything in order.

—Frances Pownall

relative to ensure continuation of both the family line and its property. Thus the family in ancient Greece could be both complex and fluid.

The nature of the family in Sparta was anomalous. Spartan women enjoyed a much higher degree of personal freedom than their counterparts in other city-states and could own land. Because boys were educated communally by the state and husbands were not allowed to live with their wives until they were 30 years old, the Spartan *oikos* was mostly composed of women.

The Roman Family

The Roman *familia*, or household, had a variety of meanings: it included not only a group of persons possessing a common kinship or legal association such as their relationship to a *paterfamilias* but also slaves and the family estate. In the strictest sense it meant all persons subject to the legal authority (*patria potestas*) of the senior male member of the family, the *paterfamilias*.

During the early republic the status of women was defined by their male relations. Upon marriage the wife would be transferred from the authority (*potestas*) of her *paterfamilias* to the control (*manus*) of her husband. The validity of a marriage was not based on the performance of a ceremony but on *conubium* (the right to enter into a marriage) and the permission of the male who wielded *potestas*. If a woman was found to be without the jurisdiction of a father or husband, she was placed under the authority of a male guardian (*tutor*).

The *paterfamilias* exercised legal authority over his children from birth. They could not own property, marry without parental consent, or

The Arch of Trajan at Benevento, 114–118 CE, celebrating the establishment of the *alimenta*. (Benjamin Lowe)

draw up a will; the father could expose (abandon to the elements) unwanted children at birth and had the power of life and death over them. Unless otherwise emancipated, children remained subject to the legal authority of the *paterfamilias* until his death. Infant mortality was high; less than half of children reached the age of five.

By the late republic there was a loosening of marital ties. *Manus* marriages became rarer, with women remaining under the jurisdiction of the *paterfamilias* even after marriage. Divorce became more common, the only obstacle being the return of the dowry (*dos*) to the family of the bride.

In order to preserve marital ties, Emperor Augustus introduced legislation in 18 BCE preventing senators from marrying ex-slaves (the *lex Julia de maritandis ordinibus*) and prohibiting adultery (the *lex Julia de adulteriis coercendis*) in an attempt to encourage Roman citizens to marry and have children, legislation under which Augustus's own daughter Julia would be condemned in 2 CE. The purpose of the Augustan legislation seems to have been to encourage the birthrate that had declined under the effects of the civil wars and the declining importance of marriage. Privileges were granted to families with three or more children.

A system to assist poorer families in raising children was established by the emperors Nerva and Trajan at the end of the first century CE. Building upon private schemes such as that of the Younger Pliny at Comum, the *alimenta* provide 16 or 12 sesterces per month to maintain

boys and 12 or 10 sesterces per month for girls. According to Pliny, the purpose of the scheme was to encourage the birthrate among lower-class families.

Early Christian Families

The evidence indicates that Jesus of Nazareth was unmarried at the time of his public career, an unusual though not unprecedented situation for a 30-year-old Jewish man of the first century CE. Many of his followers, including Peter, certainly were married (Mark 1:30; 1 Corinthians 9:5), and Paul indicates that wives often accompanied their husbands on missionary tours and could be missionaries themselves (Romans 16:3; 1 Corinthians 16:19). Paul himself was unmarried, a state he preferred because of the impending return of

Jesus with its concomitant transformation of all reality (1 Corinthians 7:25–31).

There is a strong ascetic impulse preserved in Jesus's teachings and in the teachings of Paul. While neither rejected marriage for others, their own itinerant lifestyles appear to have precluded raising families. In addition, Jesus appears to have placed allegiance to himself and his movement above allegiance to one's biological family (Matthew 8:21–22; 10:35–37; Luke 14:25–27; Mark 3:31–35). There is very little in early Christian teachings about children, most likely because the movement was infused with a sense that marriage, birth, and child rearing would all soon come to an end (Mark 12:25; 1 Corinthians 7:14, 26–28). As the decades went by, however, Christians increasingly became concerned about family issues. The New Testament contains letters attributed to Paul (1 and 2 Timothy and Titus) that are either forgeries or were written by an older Paul who had changed his views from what he had written in 1 Corinthians 7. In these later letters, the author advises remarriage for widows, marriage for virgins, raising submissive children, and mandatory marriage for Christian bishops (1 Timothy 2–5).

Other Christian authors of the second century CE put forth an ideal of renunciation of marriage, especially for women, as an avenue to spiritual and social power in the church. One example of this was the famous *Acts of Paul and Thecla*, which was not found in the New Testament but enjoyed wide popularity in the

▶ EARLY CHRISTIAN TEXT ON FAMILY

The *Acts of Paul and Thecla* was a popular apocryphal text in early Christianity that was generally considered to be fiction and thus excluded from the Bible. In this passage, the apostle Paul speaks about the virtue of chastity, which was valued by some followers of Christ as a path to a higher spiritual union with God:

“Blessed are the pure in heart, for they will see God. Blessed are those who have kept the flesh chaste, for they shall become a temple of God; blessed are the continent, for God shall speak with them; blessed are those who have kept aloof from

the world, for they shall be pleasing to God; blessed are those who have wives as not having them, for they experience God. . . . Blessed are the bodies of the virgins, for they shall be well-pleasing to God and they shall not lose the reward of their chastity.”

—Jeffrey Trumbower

early Christian centuries. Some groups, especially certain Gnostic Christians who denigrated the physical world, denounced marriage and sexual relations altogether. The proto-orthodox Catholic churches gradually developed a middle ground, one that validated monogamy and procreation for most Christians but also held in higher esteem a voluntary celibacy for those who wished to devote their lives exclusively to God. Gradually this ideal of celibacy spread from the lay movements where it had originated into the hierarchical clergy. Virginity for both men and women became prized, and Mary, Jesus's virgin mother, came to symbolize a unique combination of both sexual renunciation and loving parental care. Monogamy, albeit with widespread sexual use of concubines and slaves, was already an ideal of Caesar Augustus and the Roman empire. Christianity, however, emphasized the notion that the legal wife was the only legitimate sexual partner for a man.

The Chinese Family from the Zhou to the Han Periods

From the beginning of the Western Zhou (ca. 1045–771 BCE) dynasty to the end of the Eastern Han (25–220 CE), the structure of commoner families remained stable, while that of elite families changed immensely. During the Western Zhou and Spring and Autumn (722–481 BCE) periods, the elite lived in relatively large kinship groups that were politically autonomous and economically autarkic. However, due to the latter period's internecine warfare, by the Warring

States era (403–221 BCE) both nobles and commoners lived in nuclear families. Commoner households, while remaining small throughout this period, were subject to marked change in who their masters were and the circumstances under which they labored.

Although the details are sketchy, elite kinship groups dominated politics, society, and the economy in the Western Zhou. Among the elite, the most important kin unit was the lineage *zu*, which was a group of patrilineal kin (brothers and uncles) that lived in the same place and acted as one in war, politics, and worship. In Zhou times each lineage established a town, erected an ancestral temple, and controlled numerous commoner families. Since each lineage had its own army, land, and workers, it was autonomous and self-sufficient. These lineages were in fact merely lesser versions of the royal lineage that ruled the capital. Succession to a family's hereditary title, fief, or office was based on primogeniture. Lineages belonged to even larger ritual units known as the *zong* (clan). A clan was a larger descent group in which a number of lineages worshipped a common ancestor and paid special heed to the head of the clan (*zongzi*). Commoner households, on the other hand, were fairly small and usually consisted of nuclear families. They communally worked the land of their lord.

By the time of the Warring States, many noble lineages had annihilated each other, and rulers consolidated their states through bureaucratic rule. Sovereigns detached commoner families from their previous lords, issued them land, and collected taxes from each family. To make sure that noteworthy families no longer posed a threat to the state, nobles were given revenue from a particular area's households, but they were not given control of that region. The kingdom of Qin went even further: it decreed that fathers and adult sons could not live in the same room and doubled the taxes of households where a father resided with more than two adult sons. Consequently, during the Warring States and Western Han (206 BCE–20 CE) periods, both elite and nonelite households were uniformly small; they usually contained five or six members.

These small households were nuclear but often briefly became stem families, meaning that a

Model of a house from the Eastern Han period, 25–220 CE. (Museum of East Asian Art)

family might contain three generations (grandfather, father, and son). They were patriarchal, patrilineal, and patrilocal and employed partible inheritance whereby each son inherited an equal amount of the patrimony. Since daughters married out of the family and took part of the patrimony in the form of a dowry, they were usually viewed as less desirable unless the family had no male heirs. A daughter might then stay with her parents and marry uxorilocally (i.e., her husband would move to her commu-

nity rather than the reverse). Families would frequently split the patrimony when adult sons wed even if their parents were still alive. At the center of these nuclear families was not the father-son dyad but that of husband-wife. Elderly fathers resembled advisers rather than dictators.

By the Eastern Han period (25–200 CE), due to the weakening of the central government's authority, local elite households once again became larger, and extended families appeared more frequently. Members of the elite idealized families that could stay together for several generations. The Wei (220–265 CE) made it illegal for fathers and sons to have separate finances.

■ Introduction: Social Classes

From 1000 BCE to 300 CE, social classes worldwide became more rigidly conceptualized than in the past period. While these distinctions may not have been as extreme as in the period from 4000 BCE to 1000 BCE—there was not the disparity of wealth that was evident in Egypt between pharaoh and slave, nor was human sacrifice a prominent practice—the “rules” regarding social classes became more fixed. In Greece, the distinctions between citizen and noncitizen as well as between property

holder and nonproperty holder was paramount. In Rome, class differences manifested themselves in any number of ways, from the clothes that one was able to wear to the part one could play in governance. For both the Greeks and the Romans, slavery was a fundamental and unquestioned part of day-to-day life. In India, this is the period when the caste system becomes fully formed, a system of social organization that is still important in Hindu culture today, 3,000 years later. In China, the writings of Confucius

and the Legalist scholars articulate a rigidly organized social system. In Mesoamerica, the cultures of the Olmecs, Maya, and the people of Teotihuacan lived in highly stratified societies.

—Kevin M. McGeough

Greek Social Classes and Social Organization

Greek social classes varied enormously in composition and terminology between the different city-states (poleis), each of which was an individual unit in terms of its social and political organization. In general, however, it can be said that social organization in most city-states centered upon two basic factors: land ownership and citizenship.

When Greece emerged from the poverty and isolation in the eighth century BCE caused by the collapse of the Mycenaean civilization during the twelfth century BCE, a gradually widening gulf developed between the rich landowners, who wielded all the political power in each city-state as a result of their economic dominance, and the landless poverty-stricken majority. In order to justify their monopoly on political power, the wealthy minority propagated the notion that they were morally as well as socially superior to the nonpropertied majority.

During the seventh and sixth centuries BCE, however, new economic opportunities arising from the growth of trade and commerce allowed many nonaristocrats to become as wealthy as members of the landed aristocracy. These wealthy nonaristocrats began to challenge the stranglehold of the elite on political power, which usually resulted in violence and civil strife. In many city-states, disaffected aristocrats in the seventh and sixth centuries BCE took advantage of popular discontent with the status quo to seize power and rule as tyrants. Tyrannies generally lasted only two or three generations, when the tyrants themselves became the object of popular discontent and were overthrown. They did, however, succeed in diluting the political power of the narrow aristocracies. This led, in most city-states, to more broadly based political and social organizations in the Classical period, either oligarchies or democracies, although status was still usually tied to landownership.

> A CRITIC OF ATHENIAN DEMOCRACY

“The Old Oligarch,” author of a satirical pamphlet probably written in the 420s BCE, offers an analysis of the Athenian democracy from the perspective of an oligarchic sympathizer:

“In every land the best element is opposed to democracy. Among the best, there is least discipline and injustice, and most accurate knowledge of what is good. But among the common people are the greatest ignorance, ill-discipline, and depravity. For poverty tends to lead them into base behavior, as do lack of education and lack of learning because of lack of money, at least in the case of some people.

Someone might say that they ought not to allow everybody to make speeches and serve on the Council, but only the cleverest and the best. But in this too they are best advised, in allowing even the bad to speak. For if the good spoke and served on the Council, there would be excellent consequences for those like them, but not excellent consequences for those sympathetic to the common people. . . .

Such a way of life could never produce the best city, but this is the way democracy would be best preserved. . . . It is slaves and metics who lead the most undisciplined life in Athens; there, one is not permitted to strike them, and a slave will not stand out of the way for you. I will explain why this is their local custom. If the law permitted a free man to strike a slave or a metic or a freedman, he would often think that the Athenian was the slave and would have hit him; for, so far as clothing and general appearance are concerned, the common people here are no better than the slaves and metics.”

—Frances Pownall

Source

Robin Osborne, trans., *The Old Oligarch: Pseudo-Xenophon's Constitution of the Athenians* (London: London Association of Classical Teachers, 2004), 18–19.

It was only in Athens' democratic reforms of the fifth century that, in theory, even the poorest citizens could hold office. The wealthy minority's continuing desire to justify its status was reflected in the moral terminology used to designate the political division between oligarchs and democrats, beginning with Homer and Solon and becoming more explicit in the political texts of the later fifth and early fourth centuries BCE. In this period terms such as "the good," "the best," and "the noblest" were used to refer to the oligarchs, whereas terms such as "the bad," "the scoundrels," and "the mob" were used to refer to the democrats.

Citizenship was the other great determinant of social status. It was necessary to be an adult male citizen in order to hold political office, to vote, or to own land. Citizenship was determined by legitimate birth from a citizen father in most city-states. In Athens after 451 BCE, descent from a citizen mother as well as father was a necessary prerequisite for citizenship. Women, freedmen, and slaves remained outside the social and political organization of the city, as did *metics*, permanent residents of a city-state who were not citizens. Despite their noncitizen status, many *metics* were extremely wealthy and moved in the highest social circles, such as the Syracusan Cephalus, whose house in the Piraeus furnishes the setting for Plato's *Republic*. The Spartans were unique in determining citizenship through both birth and the successful completion of the state education system (which emphasized discipline and military training). Spartan citizenship also required male citizens to maintain a lifelong membership in a common dining hall, and citizenship could be taken away if they could not continue to make their financial monthly contribution to it. In Sparta, citizenship was limited to a degree that it was not elsewhere because it brought with it an allotment of land and the manpower to work this land for its produce. Accordingly, there were a number of inferior classes in Spartan society including the *perioikoi*, noncitizen residents who maintained personal and economic freedom but were required to serve in the Spartan army, and *helots*, who were the property of Spartan citizens and were required to work the land for them.

Etruscan Social Classes and Organization

Etruscan society was originally organized into two specific social classes, the aristocracy and the lower class, each relegated with their own characteristic roles to play within the existing social structure. The aristocracy would play a substantial role in the government, economic development, and leadership of Etruscan society. Much of what scholars know about Etruscan society is based on archaeological findings in Etruria and scholarship written by later Roman historians attempting to unravel the mysteries of Etruscan society. The most useful data in deciphering the structure of Etruscan society is from inscriptions written on their monuments, especially their famous tombs. From this evidence, it is illustrated that the growth of commerce created a rift within the Etruscan lower class, creating a social divide between those who benefited from economic expansion and those who did not. Many of the social structures prevalent in ancient Roman society were influenced by their Etruscan predecessors in Italy.

From the Villanovan period of Etruscan history (1100 to 700 BCE) to its gradual assimilation into Roman civilization (700 to 100 BCE), Etruscan society was increasingly dominated by a firmly entrenched aristocracy that exercised strict control over the political, military, economic, and religious aspects of the average person's life. In their development as a primarily agrarian society, the Etruscans gradually devel-

oped an aristocratic elite filling the top ranks of the military, the government, and the priesthood from this landed wealth. They increasingly depended on what is believed to be a substantial class of serfs who were utilized primarily as agrarian laborers. As commerce and wealth increased due to the development of Etruscan agriculture a social order gradually emerged, with the aristocracy holding most of the landed wealth and the serfs relegated to working the land and other forms of labor. This led to Etruscan cities having bifurcated neighborhoods, with the aristocracy living in luxurious stone palaces while their serfs resided in meager wood houses. Most of the archaeological remnants of Etruscan society and their long-term cultural contributions are heavily influenced by aristocratic elites rather than the common lower classes. The lower classes shared much more in common with the neighboring Italic and Latin tribes in Italy.

During the Classical (fifth century BCE) and Hellenistic (fourth century to first century BCE) periods of Antiquity, Etruscan cities began to have an increase in trade with the eastern Mediterranean Hellenistic kingdoms and Carthage in North Africa. The emergent Mediterranean trade networks established cultural and economic links between the Italian, Greek, and Middle Eastern civilizations. The wealth that trickled into the Etruscan cities led to the development of commercial elites who benefited from this process. As a result, a vibrant commercial class emerged that mirrored the merchant classes of the Hellenistic kingdoms. In spite of all these changes, commercial expansion did not yet have an adverse effect on the social structures of Etruscan cities given that aristocratic elites retained a high level of political control over daily affairs. In this respect, Etruscan society reflected the oligarchic city-states still prevalent in the eastern Mediterranean world. The Etruscan aristocracy was careful to preserve its hold over society, maintaining the societal divide that existed between them and the lower classes. Etruscan society benefited from increasing wealth as evidenced by the growing number of moderately adorned tombs of the middling classes in addition to those by the urban lower working classes. The economic and political re-

*Painted sarcophagus of Seianti Hanunia Tlesnasa, Etruscan, found near Chiusi, Tuscany, about 150–140 BCE.
(The Trustees of The British Museum/Art Resource, NY)*

lationship between the Etruscan cities with the greater Italic and Latin peoples of Italy also contributed to the growing wealth and influence of Etruscan society. With Etruscan goods traded across the Mediterranean the Etruscan cities prospered, resulting in the growing affluence of the merchant and artisan lower class.

In the Late Hellenistic period (first century BCE), social cleavages within the Etruscan lower classes appeared due to the impact of the growth of trade on the emergence of artisans and merchants. Not much information exists about the average Etruscan, and depictions of the average person's daily life do not exist, as most artifacts and relics portray only images of wealthy aristocrats, their families, and their ostentatious lifestyles. A majority of the archaeological data about day-to-day Etruscan life comes from imagery and personal items found in Etruscan tombs, accessible to those who could afford them. Many paintings and illustrations on the walls of the larger tombs illustrate worship rituals, elaborate banquets, games, ostentatious ceremonies, weddings, and other Etruscan cultural rituals. The growing importance of trade and craftsmanship to the livelihood of the Etruscans, those who were not involved in those occupations were seen as a lower class, and the once peaceful Etruscan social existence soon began to give way to social divisions and conflicts. This resulted in social cleavages that encompassed all Etruscan society, now composed of the newly developing

THE HARUSPICES

Perhaps one of the main contributions of the Etruscans to ancient Rome would be the haruspices. The haruspices were Etruscans with the duty of interpreting omens and portents in the Roman republic and the Roman empire. While the origin of such fortune-tellers or their name is not well known, it is assumed that it means someone who looks at something. Some Etruscans were acknowledged for their gift to discern the will of the gods by examining marks on the livers of animals to predict natural disasters and other catastrophes. A major part of Roman religious practices was animal sacrifices to the gods to augur good fortune for a major venture. Subsequently, the entrails of the sacrificed animals were examined by haruspices for marks on the liver, the shape of organs, or any other sign that the gods were inclined to look favorably or unfavorably on an enterprise. While such work typified interpreting signs from the gods, haruspices were never considered to be religious by the Romans. Rather, haruspices were considered to occupy a particular skill that proved useful for making decisions in political, military, and economic ventures. In this capacity, this Etruscan institution served the ancient Romans as a relic of ancient Etruscan civilization.

—Abraham O. Mendoza

rift in the lower classes between the well-to-do mercantile and artisan classes and those below them. Much of the evidence of this increasing internal social strife is found in the remains of Etruscan cemeteries from the Late Hellenistic period. The social and economic disparity between the social classes is illustrated in the tombs in terms of both the quality of the graves and the goods included within them. Much of this social strife is mirrored in the adjacent Italic and Latin communities surrounding the Etruscan cities. In spite of these growing social rifts prevalent in Etruscan society, the aristocracy maintained their hold on political power.

The eventual conquest (509–207 BCE) of the Etruscan cities by the Roman republic ultimately subsumed their social organization and structure to that typified by the Roman model, which

was heavily influenced by the Etruscan example. Having been ruled by a series of kings that constituted an Etruscan dynasty, the Tarquins (fourth century BCE), Rome was exposed to the social and economic class influences stemming from Etruria. The Etruscan aristocracy is considered to have been the model for the Roman patrician class, while the middling commercial and artisan classes along with their poorer lower orders were similar to the Roman plebeians.

Roman Social Classes and Organization

Roman social classes evolved from a dualistic social arrangement based on birth in the Roman republic (509–27 BCE) to one based on merit and wealth in the Roman empire (27 BCE–late fifth century CE). The social division of Roman classes into wealthy patricians, as the political and economic elites, and the plebeians, on the lower social end of the scale as the peasants, craftsmen, and commoners, lasted for two centuries. In later periods, social mobility was not easily attainable due to the rigid social arrangements that existed in both the Roman republic and the Roman empire between Roman citizens, subject peoples, and slaves. While there was a level of autonomy within certain client-states and provinces, Roman citizens were still regarded as the top echelon of society across the Roman dominions, having greater access to the wealth and spoils of the empire. Even within the Roman citizenry, the social status of the senatorial class (*senatores*) and the equestrian aristocracy (*equites*) persisted from the republican period of Roman history into that of the late empire.

Roman social classes in the early Roman republic were organized into two broad classes, that of the patricians and the plebeians. Only men had any sort of political agency, with women considered as wards of their fathers or husbands. Patricians were members of the wealthy or privileged class of citizens, distinguished from the plebeians, descendants of the oldest powerful families responsible for the overthrow of the Etruscan Tarquinii tyrants and the establishment of the republic in 509 BCE. Patrician status was granted only by birth into a patrician family. Plebeians consisted of the general populace of the Roman republic. Their struggle for political and legal equality with the patrician aristocracy was known as the Conflict of the Orders (494–287 BCE). During this two-century struggle, the plebeians eventually increased the political rights to which they felt entitled given their military and economic roles within the republic. Intermarriage between the classes became common. Government positions that had once been designated only for the patrician class, such as magistracies and priesthoods, eventually admitted plebeians. By 287 BCE, patrician and plebeian aristocrats (*nobiles*) emerged as the unified ruling class of the Roman republic.

As the Roman military acquired wide swaths of land in Italy, Gaul (France), Spain, and North Africa and annexed much of the Hellenistic East, the incorporation of foreign subject peoples created a different social system in the late Roman republic and through much of the empire period. Elites in many of the newly incorporated areas were given citizenship to foster loyalty to authorities in Rome. Foreign subjects not granted citizenship were allowed to retain their indigenous social hierarchy so long as they recognized the authority of Rome through the payment of tribute and allegiance.

The massive acquisition of lands throughout much of the empire increased the political and economic importance of the Roman aristocracy that composed the Senate. The farmer-soldiers who had characterized the Roman republic had been replaced by professional soldiers, loyal to their general rather than to the Senate or the republic. This vastly increased the power of the military and in the years of the empire the power of the emperors. Nevertheless, the sena-

THE TWELVE TABLES

Roman law was mostly unwritten and based on unofficial customs in the early Roman republic. This system of unwritten laws and customs allowed the patricians to maintain their political and social control of the republic at the expense of the plebeians, who had no knowledge of the law and were subject to abuses at the hands of corrupt officials, typically working for patrician interests. In the mid-400s BCE, the first official legal code, the *Lex XII Tabularum* (*Law of the Twelve Tables*) was formally established. The Twelve Tables established reverence and adherence to the rule of law as an essential value of Roman society for nearly a millennium.

This project was initiated in 451 BCE when Roman lawmakers appointed ten patrician officials (*decemviri*) to codify the first written Roman legal code. However, after a year's work, it remained largely incomplete, resulting in the creation of a new panel of officials that included five plebeians assigned the task. After many squabbles among the patricians and the plebeians on the panel, the law code was completed in approximately 450 BCE. The new legal code reinforced existing rights and legal procedures and reflected the value system of the existing patrician class in terms of property and family issues. The Law of the Twelve Tables was placed in the Roman Forum to be accessible to all Roman citizens and to ensure that plebeians had knowledge of their legal and political rights within the Roman republic.

—Abraham O. Mendoza

torial aristocracy and the equestrian aristocracy, which owned many of the lands conquered by the legions, retained much of their own political influence in Roman domestic affairs although to a lesser degree in those of the empire period.

Elites in the provinces, protectorates, and client-kingdoms retained their own social systems but were also allowed some access to political agency in Rome. The Gallic aristocracy, for example, actually became part of the Roman Senate in the second century BCE. While merchants, artisans, and soldier-farmers constituted a substantial middling class, they did not possess many of the privileges held by the higher orders (military authority, hereditary offices, honors and titles, etc.)

but still held substantial political rights guaranteed to them as citizens of Rome. Furthermore, the urban poor, the majority of subject populations and particularly slaves, were relegated to the bottom of the social ladder of the late Roman republic and much of the Roman empire period.

Slavery in Greek and Roman Society

In both Greek and Roman societies there was a heavy reliance on slave labor, and an active trade in slaves persisted to the end of the classical

Latin inscription on the Gate of Mazeus and Mithriadates at the entrance to the Agora of Ephesus, present-day Turkey. The gate is named for the two slaves who erected it in honor of Emperor Augustus who granted them their freedom. (Lyn Gateley)

► ARISTOTLE'S DEFENSE OF SLAVERY IN *POLITICS*, I.5

"Where then there is such a difference as that between soul and body, or between men and animals (as in the case of those whose business is to use their body, and who can do nothing better), the lower sort are by nature slaves, and it is better for them as for all inferiors that they should be under the rule of a master. For he who can be, and therefore is, another's and he who participates in rational principle enough to apprehend, but not to have, such a principle, is a slave by nature. Whereas the lower animals cannot even apprehend a principle; they obey their instincts. And indeed the use made of slaves and of tame animals is not very different; for both with their bodies minister to the needs of life. Nature would like to distinguish between the bodies of freemen and slaves, making the one strong for servile labor, the other upright."

world. Enslavement occurred under many circumstances, including capture in battle, bondage for debt, and seizure by slave traders; one's race or ethnicity, however, played no role. A child of slave parents generally inherited their status unless claimed by the master to become the master's child. Slaves labored in the fields of wealthy landowners, manned the oars of galleys, and toiled on construction sites. Greek and Roman householders displayed their wealth and status by the number of domestic slaves who cooked, cleaned, and otherwise served and maintained their owners' townhouses and country residences. Trustworthy male slaves handled their masters' personal and financial affairs, while attractive women were often reduced to sexual playthings. The newly enslaved sometimes possessed valuable skills—fluency in multiple languages, expertise at an art or craft, a high level of education, or athleticism—that made them especially valuable and even respected. For example, Romans prized well-educated Greek men as teachers for their children and athletic men of all ethnicities as gladiators. Business owners purchased slaves to perform manual labor ranging from mining to dock work to manuscript copying.

In Greek poleis such as Athens, even modest households had one or more slaves, a fact that

some historians see as critical in freeing the adult males to participate actively in civic matters, the precondition for Athenian democracy and the flowering of Greek culture. Greco-Roman slaves were considered personal property (chattel), though norms and laws for proper treatment (and acceptable mistreatment) evolved in classical society. Slaves could achieve freedom by informal or formal manumission either at the owners' command or through their last wills or by purchasing it from their owners.

Early Christian Society

The early Christian movement was diverse, permeating all levels of Roman society. Recent historical studies have demonstrated that from the beginning, Christianity included both rich and poor as well as Jew and Gentile among its numbers.

Christianity moved initially within Jewish communities of the eastern Roman provinces. However, it quickly broadened to include non-Jews. During the time of Paul, small Christian communities represented a cross section of society. From the second century CE onward, Christianity spread predominately throughout the pagan world. Although Christian communities were composed largely of the lower classes as was Roman society, there were upper-class members. Early Christians had a variety of occupations ranging from artisan to soldier to government official.

Until Constantine legalized Christianity in the fourth century CE, Christianity appealed to those who were on the margins of Roman society. Christian beliefs differed dramatically from traditional Roman religious thought. The worship of Roman gods was an inseparable part of being a Roman citizen. There were gods for all

➤ CELSUS'S ON THE TRUE DOCTRINE

In the second century CE, Celsus wrote an influential attack on Christianity called *On the True Doctrine*. Celsus was an otherwise unknown author, but his work generated considerable opposition among Christian theologians although a formal rebuttal to his argument was not made until a generation after its publication. Amid his criticism of Christian doctrine, Celsus claimed that Christians were comprised of the lowest, most ignorant members of Roman society. Origen of Alexandria wrote a lengthy reply to Celsus, the *Contra Celsum*, arguing at length that Christians were drawn from all ranks of society, including the educated classes. While both authors admittedly engaged in hyperbole, Celsus's work and Origen's reply represent two distinct views of Christian society. Celsus's claims are representative of many Romans; such accusations appear in other works and are addressed in many early Christian writings. Origen, on the other hand, not only tried to refute Celsus's claims but also tried to emphasize that Christianity was in fact a religion comprised of people from all walks of life.

—Lisa Holliday

aspects of life, including the welfare of individual cities and the figure of the emperor himself. Monotheism was considered by many to be atheism because it denied the Roman pantheon. Those who converted to Christianity renounced the society they lived in by their adherence to monotheistic beliefs. No longer able to participate in civic religious festivals or to sacrifice for the well-being of the emperor, Christians were viewed as outcasts by other Romans. Christian concepts of salvation and a personal god as well as its ethical teachings did not have a counterpart in Roman religious belief with the exception of some philosophical schools of thought. Initially, Christianity attracted members who were dissatisfied with their current practices. After the conversion of the emperor Constantine in the early fourth century CE, however, people began to convert because they sought to curry favor with the emperor.

Within the early Church, social status influenced one's position and responsibilities within

the community. Early communities emphasized the equality of all members, but as the number of Christians grew, this notion dissipated, and Christian communities began to mirror Roman social structure. Women went from being able to hold positions of authority within the church, such as deacon, to having relatively low status. The upper classes in particular were vital to the success of the Christian mission. From the first century CE onward, wealthy members offered their homes as meeting places for their fellow Christians. Until the third century CE, house churches were the primary means by which Christians gathered inconspicuously to worship. Upper-class members provided the funds for charitable work as well. Clement of Alexandria, for instance, urged wealthy Christians to donate generously to Christian charities, such as those that provided care for widows and orphans. Lastly, prominent members of the congregation willed tracts of land to the church. Thanks to these bequests, the church controlled a significant amount of land by the fourth century CE.

Following Constantine's reforms, which included the legalization of Christianity as well as the granting of imperial support to the religion, Christianity spread rapidly throughout the empire.

Social Structure in Late Vedic India—The Caste System

The first literary reference to the social structure now known as a caste is found in a late hymn of the *Rig-Veda* titled the “Purusha Sukta,” or “Hymn of the Cosmic Man.” In this hymn, found in the *Rig-Veda*’s tenth *mandala*, or book, the entire universe is described as having arisen

from the sacrifice of a primordial cosmic being called simply, “the Man,” or Purusha. In the verses of this hymn, a variety of natural phenomena and deities are described as coming from this being’s body parts. “The moon was born from his mind; from his eye the sun was born. Indra and Agni came from his mouth, and from his vital breath the Wind [Vayu] was born. From his navel the middle realm of space arose; from his head the sky evolved. From his two feet came the earth, and the quarters of the sky from his ear. Thus they [the deities who performed the sacrifice] set the worlds in order.”

In addition to natural phenomena and deities, the various groups making up late Vedic society are also described as having emerged from the sacrifice of the cosmic man. “His mouth became the Brahmin; his arms were made into the Warrior, his thighs the People, and from his feet the Servants were born.”

The degree to which the hierarchical grouping described in the *Purusha Sukta* reflects the caste system of later centuries is a topic of debate among scholars. Over time, the ideal of a society in which Brahmins, the intellectual and priestly class, are located at the top, followed by the warriors (Kshatriyas), the common people (Vaishyas), and the servants (Shudras) gradually became more central to Indian society, as reflected in the later *Dharma Shashtra* or legal literature of the post-Vedic, classical period. It is possible to read the *Purusha Sukta* as referring to such a social reality in the late Vedic period (the first half of the first millennium BCE). But it is unlikely that the caste system existed in its fully developed form at this stage.

Scholars have noted the resemblances between this fourfold hierarchy and similar threefold social structures found in other Indo-European societies, consisting of a priestly intellectual class, a class of warriors, and a class of commoners. The addition of a fourth class, that of servants, in the Vedic system has been interpreted by some as evidence of an Indo-Aryan invasion or migration in which the indigenous peoples of India were made into a servant class subordinate to the three Indo-European classes. But this theory is debatable, and there is evidence that the relations among the various classes of Indian society were more complex in

ancient times than a reading of late Vedic and post-Vedic texts might suggest.

The word “caste” is derived from the Portuguese *casta* (“color”), which in turn is a translation of the Sanskrit term *varna*. Varna also means “color” and is the Vedic term for the four primary categories of ancient Indian society: the Brahmins, the Kshatriyas, the Vaishyas, and the Shudras. An earlier generation of scholars saw this term “color” as further evidence that the caste system reflected an invasion of ancient India by an ethnic group with a lighter skin tone than that of the indigenous population. This theory, too, is debated among scholars, some of whom point out that the colors traditionally assigned to the four varnas are not skin tones but are derived from the system of *gunas*, or qualities, derived from the ancient Samkhya system of Hindu philosophy. Each varna is believed to have a particular set of characteristics, derived from the mix of *gunas*, or fundamental qualities, that constitute it. Brahmins are thus characterized by the *sattvic guna*, which is associated with consciousness and intelligence and symbolized by the color white. The warrior class, appropriately, is characterized by the *rajasic guna*, which is associated with ambition and energetic activity and is symbolized by the color red, and so on.

How was varna determined in late Vedic India? The system that predominated by the time of the Buddha, around the fifth century BCE, and that was already ancient by this time was a system of assigning varna through birth. The caste system, in other words, is hereditary. One is a member of the caste of one’s parents.

That such a system was questioned by some members of the society is clear from texts such as the *Chandogya Upanishad*, a part of the late Vedic corpus, that includes a story in which a young man of indeterminate caste approaches a renowned Brahmin for Vedic instruction, a privilege reserved exclusively for Brahmins. When the young man is truthful regarding his lineage, the Brahmin accepts him as a student, exclaiming, “Who but a Brahmin could speak like that!” (*Chandogya Upanishad* 4.4). One possible interpretation of this story is that the Brahmin regards caste not as a matter of birth but as a matter of individual character. Such an attitude,

➤ THE MYTHIC ORIGINS OF THE CASTE SYSTEM

In the *Rig-Veda*, there are many creation stories. One of these depicts the various parts of the universe as arising from the body parts of a cosmic deity who offers his body in sacrifice. Each body part becomes a different part of the natural world. Similarly, the text also sees the various *varnas*, or castes, as emerging from this same sacrifice.

“His mouth became the brahmin; his arms became the warrior; his legs became the common man; the servant was born from his feet. The moon was born from his mind; from his eye the sun was born. Indra and Agni came from his mouth, and from his vital breath the Wind was born. From his navel the middle realm of space arose; from his head the sky evolved. From his two feet came the earth, and the quarters of the sky from his ear. Thus they set the worlds in order” (*Rig-Veda* 10.90.12–14).

suggested in the *Upanishads*, is made explicit in Buddhist texts, such as when the Buddha is attributed with saying that “One is not a Brahmin by birth, nor by birth a non-Brahmin. By action is one a Brahmin, by action is one a non-Brahmin” (*Vasettha Sutta*).

Whether caste membership was widely viewed as a matter of individual character in the late Vedic period or whether statements to that effect are idiosyncratic and made in protest of a dominant view of caste as hereditary, by the Classical period (from approximately 320 CE to 550 CE) caste membership was most definitely a matter of birth (*jati*), as presumed in the *Dharma Shashtra* literature of that period. Over the course of time, the four main varnas of the late Vedic period became less relevant in practice than the subcastes, or *jatis*, into which the main varnas are divided: profession-based hereditary groups arranged hierarchically in terms

of the purity or impurity of the profession in question.

Changing Social Concepts under Jainism and Buddhism

Around the middle of the first millennium BCE, a movement emerged that questioned the basis of the *varna* (caste) system that had developed centuries earlier during the Late Vedic period. According to an orthodox Brahmanical understanding of this system, the human social order is a divinely sanctioned reality, inscribed into the fabric of existence. According to Jainism and Buddhism, however, caste is merely a human construct, a way of organizing society, having no divine sanction. Jainism and Buddhism share

the Vedic belief in karma and rebirth but do not view one’s membership in a specific caste as a measure of spiritual evolution. Rather, it is the character of the individual, illustrated in his or her deeds, that is important.

In the caste system as it eventually came to be practiced, society is organized into a hierarchy, with the Brahmins, the priestly and intellectual class, at the top followed by the Kshatriyas (warriors and secular leaders), the Vaishyas (the common people), and the Shudras (the servant class). Coupled with the doctrines of karma and rebirth, the result is a worldview in which one’s location in society is a measure of one’s spiritual evolution. Karma is the principle of moral cause and effect according to which one’s circumstances are the results of one’s actions, with good actions leading to pleasant results and evil actions to suffering. Because one lifetime is not sufficient time to reap the rewards and punishments that one has coming for all of one’s actions or to explain one’s current situation with respect to happiness and suffering, a corollary of the principle of karma is the doctrine of rebirth. This holds that due to one’s karma, one is born in particular circumstances to experience the results of one’s past actions. Put simply, the deeds of this life are insufficient to explain why one is experiencing the particular mix of happiness and suffering that one is experiencing. Nor at death has one typically reaped the rewards and punishments that one should expect from the deeds of this life. Thus, at least some of one’s current experiences must be due to actions one committed before this life. And the fruits of current acts that one does not experience now will come later.

Because Brahmins are at the top of the social hierarchy, the conclusion is drawn that such a fortunate rebirth must be due to highly meritorious action performed in past lives. This suggests a soul that is highly evolved, making great progress in the direction of the spiritual goal of liberation from the rebirth process. Similarly, to be reborn as a Shudra is seen as an unfortunate rebirth and consequently as a punishment for misdeeds and as evidence of a less-evolved spiritual state.

The movement that challenged the assumptions underlying the caste system was called the *śramana* (striver) movement. The *śramana*

Ceremony outside a Jain temple, India. (Tim Schapker)

movement included among its many subgroups the Jains and the Buddhists, the two shramana groups that survive as religious communities to the present. The shramanas, as their name suggests, held that individual striving, rather than the caste of one's birth, was the true measure of moral development. Anyone willing to put forth the necessary effort to become a Buddhist or a Jain monk or nun could attain liberation from rebirth regardless of the caste into which they were born. In the Jain and Buddhist communities, birth caste was superseded by individual effort as measured by one's ability to maintain religious vows of nonviolence, nonpossession, and celibacy. In these communities, monks and nuns, who could come from any birth caste, held preeminence, supported in their spiritual efforts by the laity, the householders, whose religious merit was derived primarily from their material support of the monastic community.

Social Structures of Warring States and Qin China

From the Warring States period to the Qin dynasty (403–207 BCE), the social structure of China underwent several fundamental changes, transforming from an urban-based feudal state to a full-blown territorial empire.

The Western Zhou dynasty is often characterized as a decentralized state founded on feudalism. The central court directly controlled the capital city and surrounding countryside only. Dividing the vast territory into a series of autonomous vassal states, the Zhou king assigned

them to his relatives and merited ministers. As miniature versions of the Zhou court, these vassal states enjoyed differing levels of administrative, military, and economic autonomy. Within each state, the ruler shared his political power with prominent lineages established by his kinsmen and allies. He appointed them as high officials and endowed them with fiefs (land gifts). As regional replicas of the Zhou ruler's court, these fiefs were de facto independent kingdoms ruled by Zhou nobles.

Noble lineages were the building blocks of the aristocratic world in the old Zhou dynasty. Zhou society was characterized by the classification of the population into different social ranking categories. While the Son of Heaven or *tianzi* (namely the Zhou king), the feudal lords (*zhubou*), the ministers (*qing*), and the senior officials (*dafu*) constituted the top echelons of the social structure, commoners were at the bottom. Between them were the gentlemen (*shi*), the lowest-ranking Zhou aristocrats. The ministers and the senior officials usually came from powerful lineages with independent fiefs and domains, served by the gentlemen who were related to them by blood or by marriage. The commoners, such as peasants, craftsmen, servants, and slaves, were bonded to the fief and counted as private properties of the Zhou aristocrats.

During the Spring and Autumn period (722–481 BCE), there was a greater decline in the authority of Zhou court. In quarrels among the vassal states, where larger ones conquered and annexed the weaker ones, and within states, powerful lineages fought against each other for dominance. In order to acquire a competitive edge, several states adopted profound institutional reforms, reforms that not only lasted into the Warring States period but also established the basic patterns of the social structure of the Qin dynasty.

First, the institution of feudalization was abolished, and directly administered districts were established in their stead. The fiefs of the recently dispossessed and newly conquered territories were no longer endowed to individuals. They were demarcated into commandaries and countries, governed by officials appointed by the central court. With the development of centralized administration, the original fiefs that

were dispersed over a vast territory were integrated into one political entity.

Second, once the feudal structure disintegrated, small family households emerged as the basic units of production and taxation. In the old Zhou, the peasants were obliged to work on the fiefs, and their production belonged to their lord. Beginning in the Spring and Autumn period and completed in the Warring States period, various states, one after another, institutionalized land taxation based on crop yield. This illustrates that the government tacitly recognized the land tenure of small households and that the peasants were transformed from the private property of Zhou aristocrats into the subject of the state.

Third, the state imposed universal military service on the population, extending its control into the rural hinterland. In the old Zhou, there was a clear boundary between people of the city (*guoren*) and people of the field (*yeren*). City people were supposed to join the army and defend their state, whereas people of the field, living in remote rural areas, maintained some degree of autonomy and were only responsible for paying taxes in kind and fulfilling certain corvée duties. During the Warring States period, the numerical and geographic scale of warfare was remarkably escalated, and chariots of the aristocrats were gradually replaced by mass infantry and cavalry armies. In order to efficiently recruit soldiers and collect tax to boost the ruler's military ambition, major states began to register their populations and mobilize the peasants for military service. In this way, the old Zhou world, which focused on fortified towns, was transformed into a full-blown territorial state.

Fourth, new methods of recruiting officials were introduced, which facilitated social mobility. In the old Zhou, an individual's official career was primarily determined by his family's status. During the Warring States period, because of the severe competition between rival states, a meritocracy was gradually developed, replacing the established recruitment system. Stories regarding talented men distinguishing themselves by their administrative and military accomplishments were well circulated during this time, inspiring people with obscure backgrounds to laboriously seek appointments within the various states.

Along with these reforms, there were other significant changes in the social structure: the emergence of the artisan and merchant classes. In the Zhou feudal structure, products were manufactured primarily for the nobles and were distributed according to political authority, being exchanged through the channels of gift giving, tribute, rationing, and corvée labor. With the collapse of this network, goods were produced for the market, and artisans were gradually differentiated from others and designated as a special group among commoners. At the same time, trading was also developed to circulate products and resources, which gave birth to the merchant social class. During the Qin dynasty, it became a standard understanding that the society consisted of four categories of people: gentlemen (*shi*), peasants (*nong*), artisans (*gong*), and merchants (*shang*). The gentlemen group was commonly well educated and possessed professional skills. Replacing the declining high nobilities, they constituted the main pool of the official candidates. The peasant group designated a wide range of people who worked in agriculture, including independent farmers, tenant cultivators, and hired labor. Merchants as a group were discriminated against in terms of legal status and occupied the lowest rung of the social ladder, only slightly higher than slaves, even though there are well-known stories about rich merchants who actively participated in and even manipulated the politics of the Warring State and Qin China.

Social Structures of Han China

Inheriting the political structure of the short-lived Qin dynasty, the vast territorial empire of Han China was organized into directly administered districts in hierarchical order. Under the central government, where the highest political power resided, were commanderies (*jun*). Each commandery was composed of varying numbers of counties (*xian*), the smallest administrative unit that was governed by officials appointed by the central government. Because political power was the fundamental force that both dictated the distribution of social wealth and determined social status, the whole society, based on the state, can be categorized into two major groups: the ruler and the ruled.

The ruling class included the emperor, the nobility, and government officials. The emperor, commonly referred to as the Son of Heaven, was at the apex of the social pyramid. Claiming to have received the mandate of heaven to rule the multitudes, the emperor was the source of all power, possessing the ultimate legislative, judicial, and administrative authority. Consort families and eunuchs, taking advantage of their intimate relationships with the emperor, manipulated the throne and became dominant forces who controlled the bureaucracy at the end of the Western Han and most of the Eastern Han dynasties.

The nobility consisted of imperial relatives, consort family members, and meritorious high officials. While the nobility was hereditary, their status was bestowed by the emperor and could be deprived by him at any time. A golden principle—that only members of the imperial family could be ennobled as kings and only the ones who had offered great contributions could be ennobled as marquises—had been often cited during court debates. However, it became a standard practice to elevate consort family members, especially the father and the brothers of the empress or the empress dowager, to the status of marquises. During the early Western Han dynasty, the kings had their independent courts and enjoyed economic and political autonomy in their fiefs, which presented some serious threat to the central government. Through a series of reforms, the sizes of the kingdoms were reduced, and the kings lost their power to directly rule their kingdoms. The marquises in Han China, different from the kings, seem to never possess any territorial authority over their fiefs but received a definite amount of tax revenue from the number of households assigned to them by the emperor.

While the nobility enjoyed a prestigious social status, they could only share the political power with the emperor when they were in the bureaucracy, serving as government officials. Government officials were a prominent group in Han China. First, their high incomes—including salary, gifts from the emperor, land, business, and handicrafts, etc.—brought them enormous wealth, enabling them to live extravagant lives that commoners did not. Second, they officially monopolized certain material goods according to their rank, a prestige that was protected by sumptuary laws. The special garments, carriages, horses, and attendances visibly distinguished officials from commoners. Third, officials enjoyed legal prerogatives and could not be arrested or sentenced by legal authorities without the emperor's approval. Fourth, the recruitment system of the Han bureaucracy worked to the benefit of current officials, facilitating the ability for their descendants to enter the officialdom. High officials had the privilege to appoint their children and junior relatives directly as Gentlemen of the Palace, the candidates for future positions as

officials. Furthermore, the offspring of officials were favorably recommended to the court as official candidates by the local authority, a phenomenon that was particularly noticeable during the Eastern Han.

In contrast to the ruling classes, the ruled were traditionally classified into four categories according to occupation: scholars, peasants, artisans, and merchants. Scholars were a social group characterized by blurred boundaries. It might refer to the potential official candidates who actively sought employment in the officialdom or those who refused to serve in the government but made a living through teaching or farming. The social and economic status of scholars also varied: some came from rich families that had long histories of service in the bureaucracy; some were poor and were the first generation in their families to receive an education. Due to the advocacy of Confucian ideology by the Han government, some Confucian scholars established countrywide reputations and attracted thousands of students.

Peasants' work was often celebrated as productive and fundamental to society, whereas the peasants generally occupied the lower stratum in the social structure because of their poor economic conditions. Sources show that a nuclear peasant family with around 20 acres of land could barely meet its expenses, surviving on sparse food and coarse clothing. During emergency situations, such as famine or where there was an exceptional taxation, they either had to sell their land at low price or secure loans at high interest. This meant that small landowners were often reduced to poverty, eventually becoming tenants of wealthy landowners and thus being exploited through high rents that were usually more than 50 percent of their harvest.

Little knowledge is available about artisans because of scarcity of available sources. Generally, artisans were richer than peasants and sometimes were treated as a group, as were merchants. Merchants in Han China were typically people who were involved in various businesses including trading, shopkeeping, salt and iron manufacturing, cattle and pig breeding, and money lending. In terms of legal status, merchants were discriminated against. Various edicts against them were issued by the emperor

prohibiting them from wearing silks and brocades, owning land as property, and serving as officials. However, the economic power that the large merchants had accumulated enabled them to easily transgress such regulations. Powerful merchants not only owned a large amount of land but also associated with the nobility and high officials. Some of them also successfully entered the status of officials through the purchase of positions or bribery. Their tremendous wealth was successfully translated into political power and social position, making them a privileged group comparable to the ruling class in Han China.

At the bottom of the Han society were slaves, either owned by the state or by powerful families. Criminals, their relatives, and captives of war were major sources of slaves. Both domestic slaves, who were responsible for housework, and productive slaves, who primarily labored in mines and farms, existed. Although slaves were treated as the private property of their owners and could be freely exchanged in the market, their lives were protected by the law, and it was a serious crime in Han China to murder one's slaves.

Evidence for Social Stratification in Hopewell Burials

Although the origins of the archaeologically defined Hopewell peoples are still under discussion, their cultural manifestations are generally considered to be the climax of the Middle Woodland period (2,000–1,500 years before the present) of the Eastern Woodlands region of North America. Evidence indicates that Hopewell populations either originated in western New York and moved south into Ohio, where they built upon the local Adena mortuary tradition, or they originated in western Illinois and spread by diffusion to southern Ohio and up the Illinois River and into southwestern Michigan. A number of other Middle Woodland period cultures are also classified as Hopewellian, including the Swift Creek culture, the Santa Rosa–Swift Creek culture, the Marksville culture, and the Copena culture. Across all of these Hopewellian populations several cultural manifestations are shared, linking these disparate archaeological cultures together. One of these is the evidence for social stratification in the larger Hopewellian society, stemming from the archaeological excavation and analysis of burials and burial mounds.

Archaeological evidence from Hopewell burials indicates that the nature and quantity of grave goods associated with the burials reflected an individual's status or role in the larger regional cultural system. Many of the raw materials—meteoric iron, obsidian, bighorn sheep, silver, copper, grizzly bear canines, galena, conch shell, rock crystal, freshwater pearls, sharks' teeth, mica, chlorite, and certain flint types—came from distant geographic places and are believed to have held significant social and cultural values among the Hopewell peoples. Both the quantity and the quality of the materials found in different burials from different archaeological sites across the region are considered evidence for the social stratification of Hopewell society. This conclusion is further exemplified by the fact that most of the nonlocal materials imported into Hopewell culture were often subsequently used to carefully craft even more exotic classes of highly conventionalized artifacts, such as ear ornaments, smoking pipes, panpipes, mirrors, containers, necklaces, costumes, and celts.

Crafted out of mica, this bird claw-shaped sculpture comes from a prehistoric earthwork of the Hopewell culture from the Ohio River valley. (Barbara Heller)

Further evidence for social stratification within Hopewell society comes from the range of earthen materials used in burial mound construction. For example, sod blocks and other kinds of earth used in Hopewell burial mounds apparently had important symbolic dimensions in addition to their structural properties. However, not all Hopewell burial construction incorporated sod blocks, indicating that some burials were given a higher value in the social stratification of the society, as they were constructed of a more specialized material.

■ Introduction: Ethnic Identities

The English word “ethnic” is a derivation of the ancient Greek term *ethnos*, which referred to a group of people who lived together and shared some sense of common affiliation. This was a new conceptualization of a long-held belief that certain qualities connect people into a larger community or culture. Language, religion, beliefs, and other such traits mark individuals as members of one ethnic group and mark others as not being part of that group.

As in previous periods, new ethnic groups seem to emerge from 1000 BCE to 300 CE. This is particularly noticeable in Mesoamerica, where the emergence of a number of new but related cultures, such as the Maya, appear in the region. The Maya seem to have been bound by common cultural conceptions, languages, and religious traditions rather than by political authority.

Noteworthy in the period from 1000 BCE to 300 CE is the development of ethnic identities in diaspora settings, that is, in locations other than an ethnic group’s perceived homeland. It is in this kind of setting that Judaism developed as an ethnic group, as opposed to merely a national or religious group.

—Kevin M. McGeough

Jews in the Diaspora

The term “diaspora” is derived from the Greek and simply means “scattered seed.” Yet it has taken on a specific connotation for Jews who were forced to leave the land of Israel, their homeland, and to settle in new Jewish communities outside of Israel. In 722 BCE massive deportations of northern Israelite (pre-Jewish) populations were carried out by Assyria, the strongest nation to the north of Israel. During 605–586 BCE a second stroke of warfare and deportations took place under Nebuchadnezzar II, king of Babylon. The temple of Jerusalem (the capital of Israel) was thoroughly devastated, and thousands were carried away to Babylon in exile (2 Kings 25; 2 Chronicles 36). Others fled to Egypt. When Persia conquered Babylon in 539 BCE, Jewish com-

munities may have already begun to form in Babylon and Egypt. The Jews never lost hope, however, of returning to the Holy Land. Cyrus, the Persian king, was highly tolerant toward foreign religions. He allowed the Jews to return to their homeland and rebuild their temple.

Babylon still remained a holy city during Persian rule (539–331 BCE). It was made up of mixed ethnic populations (including Jews, Egyptians, Medes, and Arabians). At another city nearby Babylon, called Nippur (on the Chebar River; Ezekiel 1:1), records belonging to a certain Murashu were found, written between 455 and 403 BCE. They deal with moneylending, mortgages, leased land, taxes, and rent. Also, in these records are found Jewish names. Here, Jews were involved in the military, were shepherds, and were lessors of land. Some Jews became agents of the Persian government, with important responsibilities of state. We also find a small number of Jewish slaves, since most at this time belonged to the lower classes. By the time of Ezra and Nehemiah (445 BCE), Jewish leaders sought to bring the diaspora back to Palestine, but many Jews in Babylon were content and had no desire to leave.

In Egypt at the city of Elephantine, Jewish military colonists built a temple for YHWH, their deity (compare to Yahweh of the Hebrew Bible). This was problematic for the Jewish religion, since Yahweh was to be worshipped only in Jerusalem. As Jews became more comfortable with their temple in Egypt, they slowly severed their ties to the homeland. Meanwhile, a specific genre of literature was being produced in Jewish culture, namely the so-called polemic against idolatry. Jews were admonished not to worship gods of foreign nations, which were merely gold, silver, stone, and wood, but rather to worship the one true invisible God, Yahweh. We know that some Jews took these admonitions seriously, while others were indoctrinated with foreign religion.

In the Hellenistic and Roman eras, the diaspora was not only affected by the homeland, but the opposite was also true as new developments from within it began to affect Palestine. The di-

aspora introduced new communal places of worship called synagogues and *proseuchae* ("houses of prayer") into Israel. Greece allowed the Jews to form their own communities called *politeumata*, which were autonomous and could practice religion freely. This freedom prevented Jews from taking part in war and paying certain taxes, though they were still not granted state citizenship. Such exemptions led to envy and strife between Greek and Jewish populations. Constant squabbling between the two was exacerbated to the point of destroying Jewish synagogues and even expelling Jews from certain cities. Jews formed major communities in Alexandria, Antioch, and Rome. In both the diaspora and Israel, Hellenism was having a heavy influence. There were many opportunities for the Jew who spoke the Greek language competently. Some who aspired to rise up in Hellenistic culture were obliged to compromise their beliefs to remain at their status. This sort of modernization led to factions within the diaspora and within Israel proper. Nevertheless, the diaspora demonstrated a resiliency to remain alive amid hardship and confrontation.

Foreigners in the Greco-Roman World

In both the ancient Greek and Roman worlds, foreigners were treated with varying degrees of tolerance and prejudice. Given the geographical scope of Greek and Roman conquests, colonization, and trade networks throughout the ancient Mediterranean world, contact with foreigners was quite common. Foreign residents lived in Greek and Roman cities or provinces in the form of slaves, traders, or permanent residents. In the imperial expansions made by both ancient civilizations, foreigners were co-opted to some extent through cultural assimilation, the granting of citizenship, and some aspects of political agency. The cultural diffusion that existed in antiquity

Relief depicting a "Barbarian" fighting a Roman legionary, second century CE. (The Gallery Collection/Corbis)

also meant that foreigners made their mark on both Greek and Roman culture and civilization.

In the Classical Greek period of antiquity, many Greeks acknowledged the existence of foreigners as different from that of other Greeks. Even though various Greek city-states were locked in a state of constant warfare, there was recognition of the common attributes of Greek culture among them. Foreigners existed outside of this arrangement and were regarded as barbarians. Greeks had also established contact with foreigners in excursions abroad due to trade, warfare, and conquest. The four kinds of foreigners prevalent in the Greek world were *metics* (permanent residents), foreigners not yet recognized as metics, temporary visitors, and slaves. Athenian metics were to have an Athenian patron and had to be registered in the local community in addition to paying a tax. They were not allowed to marry Athenians or own property. Temporary visitors included traders and merchants from abroad doing business in Greek city-states. Slaves were typically foreign people in bondage attained through war with neighboring non-Greek and neighboring Greek countries.

Perceptions of Greek cultural supremacy ebbed over time as greater contacts were created

► ROME AND THE *FOEDERATI*

During the second and third centuries CE, the Roman authorities found it increasingly difficult to protect the border from northern incursions by Germanic tribes. The Roman legions, known in their heyday as the greatest military organization of antiquity, proved increasingly incapable of defending the frontiers of the far-flung boundaries to the north. The use of provincial auxiliaries to defend the borders had also proven to be unreliable. An effective solution to this problem was to co-opt some segments of the Germanic tribes, known as *foederati*, by allowing them to settle within Roman provinces on the condition that they provide defense for the empire.

From the third to fourth centuries, the migration of Germanic tribes into the Roman empire was particularly acute given that these border tribes did not particularly remain settled in outlying Roman provinces. Some segments of the populations of the Germanic tribes did become somewhat Romanized during the course of this time. The inability of Roman society to absorb these groups through policies of assimilation and citizenship eroded any loyalty that these might have had to Rome. As the Roman state crumbled, it was readily overwhelmed by the Germanic tribes, who in combination with the cultural legacy of Rome created medieval Christian Europe.

—Abraham O. Mendoza

with countries abroad during the Hellenistic period. The expansion of the Greek world under Alexander the Great (356–323 BCE) brought Greek culture to areas previously not encountered by Greeks, such as Bactria and India. Alexander sought to integrate his dominions through cultural and political policies of marriage and cooperation under Greek and Macedonian tutelage. The successor kingdoms to Alexander's empire found themselves populated with substantial populations of non-Greeks, resulting in a significant amount of cultural assimilation within the Greek world. Resistance to Hellenistic cultural hegemony, particularly in the case of the revolt of the Maccabbes in Judea against the Seleucid kingdom (168 to 143 BCE), illustrated that not all foreigners approved of Greek cultural and political supremacy. Nonetheless, in

the Hellenistic Seleucid and Ptolemaic kingdoms there was a blending of the various cultures of the eastern Mediterranean with Greek culture to a limited extent, creating a unique and diverse Hellenistic civilization with heavily Hellenic overtones.

The Roman interaction with foreigners differed in many ways with that of the Greek city-states and Hellenic kingdoms. The Roman republic managed to absorb its neighboring Latin and Italic tribes gradually through co-opting them as citizens through alliances and warfare. Much like in Greece, Romans also practiced slavery, which brought large amounts of foreigners into Rome. In fact, many Greeks were brought in as Roman slaves due to various wars between Roman republic and the Hellenistic kingdoms. While Romans showed an admiration for Greek culture in the form of art, literature, and architecture, they also had a level of contempt for the Hellenistic Greeks. Many Greek slaves managed to achieve various positions of leadership when they became freedmen in Roman society. The co-optation of Greek society into Roman rule led to an increased level of Greek influence in Roman culture. Much of the art, architecture, medicine, and education of the Roman world were introduced by Greeks in the Late Republic and Empire periods. Many Greeks found themselves in positions of power under the rule of various emperors, such as Claudius.

The massive expansion of the Roman empire brought Romans directly into contact with various peoples throughout Europe and the Mediterranean world. Various policies of co-optation through the granting of Roman citizenship, autonomy, and political agency allowed foreigners some level of participation in Roman politics and society. Through expanded trade networks and military conquest, the Romans ruled a vast empire composed of multiple nationalities, and such policies allowed various individuals to thrive under Roman rule. Many future senators, military leaders, and emperors would come from these provinces as Romans, not as foreigners. Emperors such as Trajan (Spanish), Antoninus Pius (Spanish), Diocletian (Dalmatian), and Constantine (Illyrian) among others descended from peoples who would have been deemed foreigners in the early republic. In the course of several centu-

ries, multiple Roman provinces adopted Roman culture and became thoroughly Roman in outlook, but there were exceptions to the rule, such as Judea. Some Roman provinces retained their own cultural autonomy within the Roman empire while their elites participated in Roman culture as a sign of their growing civility.

Changing attitudes in regard to foreigners among Roman elites in late antiquity, particularly in the fourth and fifth centuries CE, illustrated chauvinistic perceptions of the Germanic tribes in the north. While many of these tribes were allowed to live within the boundaries of the Roman empire so long as they offered protection of the borders from other tribes, they were regarded as barbarians. While this perception existed since the republic, there had been little effort to co-opt these groups in the same way as peoples such as the Gauls and the Greeks. Some Germanic individuals, such as the Roman general Stilicho (Vandal), were part of the late Roman leadership, but mostly German tribes were seen as foreign and undesirable elements. The failure to assimilate these groups into greater Roman society has been viewed as one of the many reasons that brought the Roman empire to a gradual end in the late fifth century CE.

Non-Chinese in China

Although Chinese historians often portray China as having been culturally homogenous since ancient times, the situation has actually been much more complex. Determining who was and was not Chinese can be very subjective, but one powerful indicator of ancient difference is language. Groups that did not speak Chinese likely differed (culturally) in other ways from the ancient Chinese population. The Yue and Xiongnu were two non-Chinese-speaking groups that emerged as powers within what is now known as China in the first millennium BCE.

IMAGE FROM WU HUNG

(Feng, Yunpeng and Feng Yunyuan 1821: "Shi Suo," 3.62)

The mural above is from a shrine dating to the mid-second century CE in Northeast China. It depicts a Xiongnu prince, Jin Midi, who was a hostage at the court of Wudi (140–87 BCE). According to Eastern Han authors, Wu had a portrait of Jin Midi's deceased mother made and displayed it in the palace. Whenever Jin Midi would go to the palace, he would pay his respects and weep until tears had drenched his garments. The fact that a Xiongnu prince was held up as a filial exemplar by Han elites reveals that at least some of them believed that their enemies shared the same basic moral impulses.

—Miranda Brown

The origins, identity, and geographic parameters of the Yue are a source of scholarly controversy. The Yue presumably lived south of the Yangzi River, possibly living as far as the southern and southeastern coasts of present-day China. The Yue probably engaged in wet rice agriculture and spoke a language that belonged to the Austroasiatic language family, one distinct from the language spoken by the inhabitants of the Central Plains. The first references to the Yue occur in the *Spring and Autumn* annals (*Chunqiu*). It appears that by the fifth century BCE the Yue had emerged as a regional power after King Goujian (r. 496–465 BCE) conquered another

southern state, Wu. The power of the Yue, however, came to an end in 333 BCE when they were conquered by the southern state of Chu.

The Xiongnu were a nomadic group living in the northern and northwestern regions of the Han empire, possibly speaking a Turkic or Altaic language. Little is known of Xiongnu culture or language, as no contemporary records of the Xiongnu by Xiongnu authors survive. Some archaeological evidence now supplements information presented in Han dynasty (206 BCE–220 CE) *Historical Records (Shiji)*, circa 90 BCE. The Xiongnu figure in early records and appear to have been a menace to states in the Central Plains before the unification of China in 221 BCE. Late in the third century BCE the Xiongnu formed a confederacy under the leadership of Maodun. From this time on, the Xiongnu presented a formidable threat to the Han empire. Although they signed a treaty with the first Han emperor in 209 BCE, they frequently raided border areas. As a result, the Han court was forced to make conciliatory gestures, such as providing luxury goods and Han princesses as consorts to the Xiongnu. This policy of appeasement was known as the *heqin* policy. The costs of appeasement, however, were high. Historians estimate that the appeasement cost no less than 8 percent of the gross national product of the Han empire. Seeing that appeasement was not only costly but also ineffective, the Han emperor Wudi (r. 145–87 BCE) decided to pursue a more aggressive policy toward the Xiongnu. Sending large armies into Central Asia, Wudi established military colonies that protected the Han population against raids and pressured the Xiongnu and other local tribes into accepting Han suzerainty. In order to pay for his armies, Wudi instituted state monopolies on salt, iron, liquor, and coinage. But after his death in 87 BCE, the court held a series of debates known as the Debate on Salt and Iron (Yantielun) in which Wudi's policies were discussed. Not long afterward, his policies were discontinued. Fortunately for the Han, the Xiongnu tribe split into two federations and engaged in internecine warfare, with one side allied with the Han. From this time on, the Xiongnu ceased to pose a serious military threat.

The Tocharians

The Tarim basin is a vast expanse, over 150,000 square miles (388,000 square kilometers), located in what is now China's far west. In antiquity, this was one of the major locations that connected China with South Asia and the Middle East, and as archaeologists continue to work in this region, evidence for the intermingling of groups here points to a complicated history. From at least 1000 BCE (and perhaps as early as 2000 BCE) and lasting until about the second or third century CE, a group of people known to scholars as the Tocharians inhabited this region.

The name "Tocharian" is based on the language that these people spoke. Tocharian was an Indo-European language and was the easternmost spoken Indo-European language. There are actually two branches of Tocharian: eastern and western. Archaeological discoveries in the twentieth century brought to light textual evidence of this language—written in a unique writing system—dating to the eighth century CE. Linguistic analysis has shown that this language was spoken in the Tarim basin much earlier and thus has been associated with the Tocharians mentioned in Greek sources. This clearly Indo-European language suggests that cultural contacts between Eurasia and the Far East were substantial in the period 1000 BCE to 300 BCE.

Further complicating the issue are the hundreds of mummies that have been excavated in the Tarim basin, dating to the period 2000 BCE

➤ GENETICS AND NATIONALISM

The genetic study of the mummies of the Tarim basin has been controversial, since it involves a number of nationalist concerns. The Chinese government has been reluctant to acknowledge the possibility that non-Chinese populations once inhabited this region. The Uighur people, who currently live in the Tarim basin, some of whom have developed anti-Chinese impulses, have also contested the results but on the grounds that the Tarim Mummies should be related to

them. However, for the most part, the Uighurs have embraced the genetic evidence as evidence that their people have ruled the region, independently of the Chinese, for centuries. In fact, the evidence does not seem to suggest that these mummies were related to the Uighurs either. What is not controversial is that the issue of who the Tocharians were is complex and far from settled.

—Kevin M. McGeough

to 300 CE. These mummies were well preserved in the arid Tarim basin, and physical anthropologists have been able to do extensive genetic analysis of the human remains. Generally, these mummies look more like what one would expect Europeans to look like in this time period; many of them had blond or reddish hair. Other analyses have shown that many of these mummies have features that could be associated with South Asia as well. DNA analysis has further shown that these people were, in fact, genetically linked to Europeans, although many scholars contest these findings. Since this genetic link is not present in the modern-day inhabitants of the region, if this is accurate it is likely that its extinction is related to the extinction of the Tocharian language as well.

The Greek historian Strabo (63/64 BCE–24 CE) writes about the Tocharians, associating them with the nomadic Scythians, and discusses how they participated in the destruction of the Bactrian kingdom. Some have suggested that Chinese sources refer to them as Daxia, although this may actually refer to Bactria in those texts. Whatever the case may be, their location on the Silk Roads brought them into contact with people from throughout Asia, Europe, and Africa.

Han People of China

Since the last days of the Roman republic, those in the West have been calling the land of silk in East Asia "China" after "Qin" (Ch'in in the old way of transliterating Chinese), the name of the dynasty of the first Chinese empire; hence, the people there are "Chinese." The majority of the people living in China have been calling themselves "the people of the Han," after the long-lasting Han dynasty (206 BCE–220 CE), since at least 100 BCE. The Chinese call their language group Hanyu and call characters used to write Hanzi. Those who spoke the different Chinese languages from this language group, used the Chinese characters, learned Confucianism (in family affairs and governing outlook), and farmed millet, sorghum, wheat, and rice were, by self-made definition, Han Chinese. Yet Chinese historians have constantly made it clear that even nomadic peoples in the north who

► THE CONCEPTUALIZATION OF THE HAN IN MODERN CHINA

The Han Chinese make up over 90 percent of the population of today's China but are a majority in less than half the country. But when the Chinese Communist Party government wants to punish an ethnic group—like the Tibetans from the 1960s through today—or when there is an economic boom that brings jobs to an area—like in Xinjiang Province since the year 2000, where the mostly-Muslim Uighurs live—tensions can grow between the regional majority ethnicity and the Han into animosity. In July 2009 a series of confrontations between Uighurs and Han led to riots in which 150 people died and over 800 suffered injuries. Since then, Uighurs have been arrested for using syringes to stab or threaten Han Chinese; over 500 assaults with needles have been reported to authorities within a two-month period.

—William Ashbaugh

copied Han Chinese languages, writing, and ways of living should not be considered Han Chinese. This emphasized difference includes the mixed Han/nomadic founder of the Sui dynasty, the Mongols and their Yuan dynasty, and the Manchu and their Qing dynasty. Han Chinese today make up over 90 percent of the population of the People's Republic of China's (PRC) plus a significant majority of overseas Chinese.

The arguments in anthropology revolve around whether Han Chinese are an ethnicity or simply a self-identifying group. There seems to be some correlation with DNA for those calling themselves Han Chinese yet not for all, and this genetic marker is also found among Japanese and other East Asians. In terms of symbolism, some scholars today look at the flag of the PRC not as the color of communism used to govern Mao Zedong's state—red for socialism, the big star for the Chinese Communist Party, and the four small stars for the classes helping the revolution—but instead as a symbol of the Han dynasty (red was its traditional color), with the largest star the Han majority and the four small stars the larger minority groups (the Manchu, the Mongols, the Uighurs, and the Tibetans). Of course, this leaves out the Zhuang of southern China, considered to-

day by China's government the largest of all minority groups with 16 million people, and the Hakka, who before the twentieth century were considered non-Han. Today, the PRC considers China's population a mix of fully 56 ethnic groups, again neglecting the Hakka. Yet among the myriad ethnic groups are many who look, act, and behave more like their neighboring Han Chinese than do two groups of Han Chinese living 1,000 miles (1,610 kilometers) apart; not all people calling themselves Han Chinese are alike in dress, diet, or discourse.

The End of the Jomon in Japan

The Final Jomon period began circa 1000 BCE and gradually ended between 800 and 300 BCE. The downward trend in settlement size continues going from the Late Jomon period through the Final Jomon period. Further, while settlement size decreased, the number of sites also decreased. For example, in Aomori prefecture there are 1,518 sites that date to the Late Jomon period, 56 of which are settlement sites. Those 56 settlement sites had a total of 420 pit houses. For the Final Jomon period 724 sites have been discovered, 16 of which appear to have been settlement sites. A total of 33 pit houses have been discovered at these 16 sites. This trend is mirrored elsewhere throughout the Japanese Archipelago.

This paucity of settlements has led many to believe that the Final Jomon people were mobile foragers and probably depended on hunting for subsistence. The abundance of lacquerware from Final Jomon sites, though, indicates that at least part of the population was sedentary for

several months out of the year, so they could produce lacquerware.

One example of a Final Jomon site in north-eastern Japan is the Kamegaoka site in Aomori prefecture. Although the site has been looted over the centuries, excavations at the site have yielded a large number of spouted vessels in the Obara/Kamegaoka style, lacquered wood and pottery, and numerous clay figurines. Due to looting, it was uncertain how many pit houses existed at the site, but the presence of fishhooks, fish harpoons, and chestnut and walnut remains suggest that the site was also used as a residence. Another Final Jomon settlement site was found at Aota in Niigata prefecture. This was also a waterlogged site that yielded large amounts of basketry, lacquered objects, and organic remains.

Stone circles and other stone monuments continue to be built in the Final Jomon period. One example is the stone circles at Oyu, Aomori prefecture. The Manza site at Oyu consists of two concentric stone circles with a diameter of approximately 164 feet (50 meters). The outer ring also contains a sundial type of stone circle. At Tenjinbara in Gunma prefecture there is a stone circle with three upright stones nearly 3.2 feet (1 meter) in height. The upright stones are oriented toward Mount Myogi and sunset at the spring equinox.

Another type of ritual site found dating to the Final Jomon period is wood circles. Examples have been excavated at Mawaki in Ishikawa prefecture and Teraji in Niigata prefecture. At these sites, large wooden posts were used to enclose a circular space. It is uncertain if the wooden circles served the same purpose as stone circles. Their purpose may be quite different, since there is no evidence of burials associated with these structures.

A variety of studies on the funerary practice and rituals during the Final Jomon period have been done. Grave goods appear in about 50 percent of the Final Jomon burials. For at least the Kamegaoka culture in northeastern Japan, the grave goods are seen as marking elite status. The presence of grave goods in approximately 20 percent of the graves of children may indicate hereditary ranking.

At the Final Jomon cemetery of Yudeno in Akita prefecture, the grave pits are aligned on either a north-south axis or an east-west axis.

THE JOMON IN HOKKAIDO

While the Jomon came to an end in most parts of the Japanese Archipelago, this was not the case for Hokkaido. In Hokkaido, the time period from circa 300 BCE until circa 500 CE is known as the Epi-Jomon period. The inhabitants of Hokkaido at this time still made cord-marked pottery, used stone tools, and had a subsistence economy based on hunting and gathering.

By 500 CE the Okhotsk culture is present along the coast of northern Hokkaido. This culture is characterized by a heavy dependence on marine resources; the use of deep pottery decorated with appliqué, incision, and stamping; and residence in pentagonal- and hexagonal-shaped houses. The origins of the Okhotsk culture are debated by archaeologists. The Japanese archaeologists U. Maeda and K. Yamaura see the cultural complex originating in either Sakhalin Island or northeastern Hokkaido. Others have argued that the Okhotsk culture developed in the Amur River region and migrated southward to Sakhalin and northern Hokkaido. Skeletal analyses do indicate that at least part of the population in the Okhotsk settlements came from outside of Hokkaido.

Elsewhere in Hokkaido is the Satsumon culture. This culture is characterized by the use of round pit houses, pottery with brushed decoration, and small mounded tombs. In terms of subsistence, the Satsumon cultivated wheat, sorghum, millet, and beans; fished for salmon; and hunted deer and other wild animals.

—Mark E. Hall

Given that the summer and winter solstice is oriented along a north-south line and the spring and autumn equinoxes are oriented along an east-west axis, the grave orientation may indicate the season that the grave was dug. A similar situation is at the Final Jomon cemetery of Oshide in Gunma prefecture.

In terms of studies of the skeletal remains, tooth crown measurements and nonmetric cranial traits have been used to address postmarital residence patterns during the Final Jomon. Studies of the skeletal remains from Ikawazu shell midden in Aichi prefecture indicate that there was a bilocal postmarital residence pattern. This means that community members could marry

one another and remain in the community. Similar results were found for the Final Jomon cemetery at Tsukumo in Okayama prefecture.

Archaeologists see the elaborate crafts, ritual sites, and burial patterns as evidence for increasing social complexity during the Final Jomon period. The scope of the ritual monuments would have required the labor of numerous people, and someone would have had to organize the construction of the monuments. The grave goods in the burials are suggestive of a weakly ranked society.

Two distinctive style zones are evident in the pottery from this period. In northeastern and eastern Japan, burnished pottery with limited zones of cord marking demarcated by incised lines is prevalent. The characteristic styles are Fusenmon, Maeura, and Obora/Kamegaoka. In the southwest, a variety of new vessel forms having continental parallels appear. The characteristic Jomon cord marking is replaced by black burnishing.

As noted above, the Final Jomon inhabitants are believed to have been mobile hunters and gatherers. The elaborate harpoons and fishhooks plus the shell middens in the eastern Kanto region are all evidence for the exploitation of marine resources. In central and southwestern Japan, analysis of floral remains from several Final Jomon sites has yielded the following cultigens: beans, bottle gourds (*Lagenaria*), barley (*Hordeum vulgare*), and rice. It needs to be stressed that these cultigens comprised only a small portion of the Final Jomon people's diet. Two sites that show evidence of rice cultivation while Final Jomon pottery was still in use are Itatsuke in Fukuoka and Nabatake in Saga prefecture. A short transitional phase, dubbed the "Initial Yayoi," marks the gradual adoption of wet rice agriculture and the gradual development of Yayoi-style pottery.

Outside of Hokkaido and Okinawa, the Final Jomon period gradually came to an end. Wet rice agriculture, metallurgy, and Yayoi-style material culture were gradually adopted between 800 and 300 BCE.

The Celts

Historical accounts on the origins of ancient civilizations typically focus on the Mediterranean world, especially the contributions of the ancient Greeks and Romans, and tend to overlook the myriad of Celtic peoples (collectively called Keltoi) to the north. This oversight of the Celts may be attributed to their less-developed political and military structures, leading to frequent defeats in battle and eventual relegation to the fringe areas of Britain and northeastern France. Furthermore, lacking any recorded tradition, their story was most often told by their more literate conquerors. Yet the Celts, whose settlements (signified by the prefix "Gal") stretched from the present-day countries of Spain (Galicia), Turkey (Galatia), Poland (Galacia), and Ireland (Galway), can be credited for having the first truly European culture.

This preclassical civilization originated with the dawn of the Iron Age, around the early eighth century BCE, and centered around the nexus of Europe's four great river systems: the Rhine, the Rhone, the Danube (Inn), and the Po—in the Alps. Hence, the early Celtic cultural epoch is called Hallstatt (750–500 BCE) from the site near Salzburg, Austria, where archaeologists uncovered the most abundant remains of this period. These peoples, transformed by developments of the Neolithic revolution, made horse-shoes, iron-rimmed wheels for chariots, and iron plows. Later Celts are identified as La Tène (500–52 BCE) from discoveries of their remains at Lake Neuchatel near Bern, Switzerland.

To a great extent this transformation resulted from the incursion of the Scythians, a people from southern Russia, in the sixth century. Thereafter, the Celts established trade networks, exchanging such commodities as salt, copper, tin, cattle, iron, pork, and slaves. They also adopted the Scythian custom of wearing trousers (*bracae*) and relying more on the horse as a vital component of their economic and military system. Such modern cities as London, Paris, Geneva, Marseilles, Vienna, Milan, Bonn, Budapest, Belgrade, and Ankara originated as Celtic settlements from this period. It was a tribe called the Parisii who first settled Paris, the Remi who founded Rheims, and the Belgae who resided in what is now Belgium and the Helvetians in Switzerland. But the most distinctive regions were Cisalpine Gaul (now northwestern Italy) and Transalpine Gaul (present-day France).

It was likely the horse that had the most profound impact on Celtic culture. The horse not only provided greater mobility in warfare, in contrast to the deliberate movements of the Roman infantry, but also imparted to the Celts a greater love of freedom and individuality. The Celts became impetuous, spirited, intuitive, mystical, melancholy, and more prone to follow individual proclivities than those of society. The typical warrior is depicted with long hair and a drooping moustache, fierce in battle and emotional and having an obsession for war and an ungovernable temper.

In contrast to the balanced and orderly configurations of the Greeks and Romans, Celtic art was flamboyant and meant to be enjoyed rather

The Gundestrup Cauldron is a richly decorated silver vessel found in Denmark, thought to date from the second or first century BCE. The cauldron may have been designed by Celts of the La Tène culture, though some scholars believe it may be the work of Thracians from southeastern Europe. (Jupiterimages)

than contemplated. The Celts loved jewelry, bright colors, plaids, tartans, and intricate designs, curves rather than straight lines. They liked to decorate their chalices, swords, broaches, bracelets, and especially torques, a distinctive Celtic appurtenance. Their art was abstract, with circles and faces predominant. Celtic pottery and weapons are among the most decorative in the ancient world. Even their bodies were tattooed or dyed in bright colors, and warriors, not unlike the ancient Spartans, would enter battle naked, believing that this would provide protection. The courts of Celtic chiefs were graced with jugglers, buffoons, and bards, with the latter regaling listeners with stories about their leaders' valor in war and mercy in peace and tribal sagas that blurred the bounds between reality and myth.

Celtic religion was polytheistic, but the principal deity was the horse goddess, Epona, from which the Latin equus and English equestrian are related. The druids served as custodians of the faith, dictating the nature of sacrifices, regulating individual conduct, and divining the future. Women played a more prominent role than in most early societies. They were not only priests but could also own and inherit property and become warriors and communal leaders.

► HOW DO THE ANCIENT CELTS RELATE TO MODERN CELTS?

In the aftermath of Roman conquests, Celtic culture was largely obliterated. Despite further devastation by the Germanic Franks and Anglo-Saxons in France and England, respectively, Celts still made up the great mass of the population. Only in the peninsulas and islands of northwestern Europe—Wales, Scotland, Ireland, Brittany, Cornwall, and the Isle of Man—did Celtic nationality and culture survive and even flourish. Ireland and Scotland became early centers of Christian fervor and proselytism. But the growth of stronger political and military institutions in France and England made steady inroads on the independence and vitality of the Celts. While the Cornish and Manx were easily absorbed, other Celtic nationalities engaged in centuries of fruitless insubordination to their superior and better-organized enemies.

Eventually they were conquered and subjected to successive acts of union: Wales (1536 and 1543), Scotland (1707), Brittany (1789), and Ireland (1801). In the face of determined efforts to suppress resurgent Celtic nationalisms in the nineteenth century, these countries both compromised and retained their cultural identities. The latter sometimes took a violent turn as in Ireland, which won its independence from England after an early-twentieth-century rebellion. Subsequently, a Celtic diaspora resulted in settlements around the world, but variations of the native tongue are spoken by only slightly more than two million people. While Brittany remains an integral part of France, the creation of a Scottish Parliament and a Welsh Assembly in the 1990s brought political autonomy from England.

—John D. Fair

The most enigmatic Celtic attribute was the significance placed on heads, which were collected as trophies in battles and used to decorate horses and houses. The head no doubt represented the essence of one's being.

The Celtic political and social system was based on the tribe, led by a chief or king, and loyalties tended to be personal rather than institutional. Success or failure often hung in the balance. Much depended on the king's leadership qualities, and youthful energy was valued over the wisdom of age. Disgrace in battle or some other adversity might lead to a ritualistic killing whereby the king would be slain by a priest and the fortunes of the tribe divined from his convulsions or emissions of blood. A new leader might be chosen by a duel or the chase of a wild boar, the winner being rewarded with the animal's thigh and elevation to the kingship.

Generally, it was the political and military diffusion and the nomadic nature of the Celts that was most critical to their fate. Despite their fierce attacks and obsession with war, it was the disciplined Roman legions, not the Celtic horsemen, who ultimately prevailed. The former responded to sporadic raids (Rome was sacked in 378 BCE and Delphi in 279 BCE) by decisively

defeating the Gauls in 225 BCE at Telamon. The Celts' greatest misfortune, however, stemmed from their encounter in the first century with Julius Caesar. Alleging provocation from the Helvetians in the nearby Rhone Valley, he launched an eight-year conquest of Gaul that featured dozens of battles, the destruction of many settlements, and the massacre of countless Celts. The conquest eventually led to Caesar's elevation to supreme power in Rome.

A final defeat occurred in 52 BCE when Vercingetorix, chief of the Averni tribe, formed a large confederation of Gauls. But he utilized the un-Celtic strategy of defense, allowing his army to be trapped in a fortress at Alesia (near Dijon) and besieged by Caesar's smaller army within a circumference of 9.5 miles (15.3 kilometers). Despite Celtic reinforcements that surrounded the Romans within a 14-mile (22.5-kilometer) perimeter, the latter, through a combination of walls, ditches, booby traps, and firm discipline, were able to surmount the double siege, conquer their Celtic foes, and capture Vercingetorix. The remaining Celts were either assimilated or relegated to the fringes of the civilized world.

The Peoples of Mesoamerica

The term "Mesoamerica" was introduced by German anthropologist Paul Kirchhoff in 1943. Literally meaning "Middle America," the concept encompasses different social, cultural, and economic characteristics that were and still are partially shared by indigenous peoples living in the modern countries of Mexico, Guatemala, Honduras, Belize, El Salvador, western Nicaragua, and Costa Rica. This vast geographic area includes a great ecological diversity, perhaps the most striking feature of Mesoamerica. Economic interdependence is in fact the primary factor that led historically to the formation of a common heritage.

Northern Mesoamerica is characterized by a particularly dry climate with very low precipitation, concentrated in the month of August. The highland regions of central and southwestern Mexico, on the other hand, are very fertile, and intensive agriculture was practiced since the first millennium BCE. The southern stretches of Mesoamerica as well as the Pacific Coast are tropical; constant humidity and high temperatures create a thick forest.

Following common evolutionary theories of his times, Kirchhoff summarized Mesoamerican characteristic features as markers of a greater social complexity in comparison to neighboring regions of North and Central America. In ancient Mesoamerica, settled lifestyle developed from the intensive cultivation of the maize plant. As a consequence, state structures such as Maya city-states in the south and the vast empire of Teoti-

CHRONOLOGY—MESOAMERICA

Gulf Coast: Olmec 1200–600 BCE

Central Mexico: Teotihuacan 200 BCE–600 CE

Tropical Lowlands: Maya 400 BCE onward

huacan in central Mexico as well as large urban settlements arose. Typically, the ceremonial core centered on a plaza (open gathering place) surrounded by large raised platforms and temples, often taking the shape of a stepped pyramid. Other striking features of Mesoamerican complexity are the glyphic writing system, which combines pictographic and phonetic elements and long-distance trade, carried out by human porters (no pack animal existed in prehispanic Mesoamerica). The religious life was structured along a ritual calendar of 260 days and included human sacrifice and the ballgame, a team sport that was played in ceremonial centers during special ritual occasions.

Later studies revised Kirchhoff's model, but the general validity of the term "Mesoamerica" to designate a specific geographic and cultural region has not been questioned. Among the most important changes in the current definition of Mesoamerica are its geographical boundaries, recognized to be much more flexible and fluctuating depending on the historical period. The people of Mesoamerica's northern borders, encompassing the modern northern states of Mexico and the American Southwest, engaged in trade networks with the Mesoamerican core. They exchanged important luxury items, such as turquoise. In the south, tropical bird feathers, animal pelts, and cacao were exchanged with peoples from the isthmian region. In both cases, the symbolic value assigned to the consumption of raw and manufactured materials resulted in the creation of a common cultural heritage.

Knowledge of early Mesoamerican civilizations and their cultural peculiarities and historical developments in this period derives only from archaeology. Excavations and surface evidence contribute to the understanding of subsistence

systems (i.e., agricultural products, exchange of primary sources and crafted materials, and the general distribution of settlement patterns). Maize, beans, and squash were cultivated on *chinampas* (raised fields) in the plateau of central Mexico, while hill terraces were more common in the mountainous regions to the south. Obsidian, an intrusive volcanic rock, was the only cutting tool employed in ancient Mesoamerica. Obsidian sources can be traced easily through an analysis of their chemical composition, allowing for a general understanding of trade routes and exchange network throughout Mesoamerica.

Assessments of political institutions and class structures are quite difficult to make based solely on an analysis of material culture. The deciphering of the Mayan script, beginning in the 1960s, has allowed the reconstruction of dynastic histories, warfare activities, and ceremonial practices in the southern lowlands of Mesoamerica. Inscriptions are generally found on stone

monuments that were erected to commemorate events of political importance.

■ Introduction: Law

The period from 1000 BCE to 300 CE is a Classical period in terms of legal traditions. The legal traditions of China and India are rooted in this time period, and those components of the Western legal tradition that are rooted in Greek and Roman jurisprudence find their origins in this time. Even biblical traditions, which reflect traditions much earlier than this period, were first codified within the biblical text during this time. Written laws and codified legal practices became common throughout much of Asia and southern Europe in this transformative period.

—Kevin M. McGeough

Biblical Law

According to rabbinic tradition, there are 613 laws (Hebrew *mitzvot*) in the Torah (Genesis, Exodus, Leviticus, Numbers, and Deuteronomy), the first and most sacred part of the Hebrew Bi-

ble, thought to have been given to Moses by God at Mount Sinai. These laws cover a wide range of topics, including religious observance, criminal behavior, civil disputes, and even proper washing and health codes. The German scholar Albrecht Alt divided the laws found in the Torah into two broad categories: casuistic (case) law and apodictic law (commands). Casuistic law generally follows an if-then format; Exodus 22:1, for example, stipulates that "If a man steals an ox or a sheep and slaughters it or sells it, he shall pay five oxen for the ox and four sheep for the sheep." Scholars have long noted that a number of the casuistic laws found in the Bible show similarities to other ancient law codes, particularly those of Mesopotamia; some scholars have suggested that the biblical laws may have been influenced by these older codes.

Apodictic law, on the other hand, is concerned with absolute, necessary truths, commands that are not dependent on an if-then formulation. Alt theorized that such law was an

Israelite innovation; while this may be overstating the case, it is true that this commandment formulation is not emphasized in other ancient Near Eastern law codes.

The most famous of these apodictic laws are, of course, the Ten Commandments; the first of these contains a prologue explaining why God has a right to impose these laws on Israel (because He brought them “out of the house of Egypt, the house of bondage”). These commandments appear in their full form twice in the Bible, in Exodus 20:2–17 and Deuteronomy 5:6–21. Interestingly, while nine of them are virtually identical, the two recitations differ in their presentation of the fourth, which enjoins Sabbath observance: in Exodus 20:9–11, Israel is commanded to rest on the Sabbath because God rested on the seventh day after creating the world during the previous six (cf. Genesis 1). In Deuteronomy 5, on the other hand, the creation is not mentioned; instead, the Sabbath is to be observed to commemorate the deliverance of Israel from slavery in Egypt.

These differences, along with other discrepancies between the Deuteronomic laws and those found in Exodus through Numbers (e.g., the instructions for tithing found in Numbers 18 and Deuteronomy 12 and 14, or the emancipation of Hebrew slaves in Exodus 21 and Deuteronomy 15) suggest that far from being a single, unchanging code delivered to Moses during his lifetime, biblical law evolved during Israel’s history, changing to reflect different historical contexts and the perspectives of different groups. The Exodus version of the commandments, for example, is thought to have been transmitted by the priests; it is logical, then, that it alludes to Genesis 1, the priestly story of creation. The biblical authors apparently felt at least an element of creative freedom in reporting even these, the most sacred of God’s commands to His people.

➤ EYE FOR AN EYE—JUSTICE IN ANTIQUITY

“If a man put out the eye of another man, his eye shall be put out. If he break another man’s bone, his bone shall be broken. . . . If a man knock out the teeth of his equal, his teeth shall be knocked out.”—*Code of Hammurabi*, lines 195–196, 200 (Old Babylonian, eighteenth century BCE, translated by Leonard W. King)

“If a man injures his neighbor, just as he has done, so it shall be done to him: fracture for fracture, eye for eye, tooth for tooth; just as he has injured a man, so it shall be inflicted on him.”—Leviticus 24:19–20 (NASV)

—John Walton Burnight

Greek Law

The Greek word for both “law” and “custom” is *nomos*, and so it stands to reason that written law codes developed out of customary rules transmitted through oral tradition. The social and political pressure placed on the elite by the middle classes during the sixth century BCE led to the gradual process of writing down the laws. This was most likely done in order to mitigate accusations of arbitrary judgment by the aristocratic magistrates.

The first law code in Athens is traditionally attributed to the shadowy figure of Draco (even his existence is doubted by some) in 621–620 BCE, probably in response to a failed attempt at tyranny a decade earlier. Draco’s law code was remembered as exceedingly harsh (draconian), with death prescribed as the penalty for even trivial offenses. With the exception of its regulations on homicide, Draco’s law code was superseded in 594–593 BCE by the reforms of Solon. Solon established a people’s court of appeal (the *Eliasia*) against the judgments of the magistrates and made it legal for any citizen to launch a prosecution on behalf of an injured party or of the community as a whole. Previously this right had been limited to the injured party or his family. This measure gave the lower classes recourse

Solon (depicted here), using his power as archon, dictates the new laws of Athens. Mounting conflicts between the rich and poor, added to the oppressive laws of the former tyrant, Draco, called for rapid legal reform in seventh-century Athens. Solon was picked as the arbiter of these new laws. (Ridpath, John Clark. *Ridpath's History of the World*, 1901)

against the elite in the short term but in the long term contributed toward Athens' reputation of litigiousness. Solon's law code was inscribed on wooden pillars and erected for all to see. It remained the basis for Athenian law throughout the Classical period.

After the democratic reforms of Cleisthenes, the Athenian Assembly began making laws. This process, naturally, was piecemeal and led to the unsystematic grafting of new laws onto old ones, making it difficult to keep abreast of what laws were currently in force. The disadvantages of this system apparently became obvious during the oligarchic revolution of 411 BCE. During this period the restored democracy of 410 BCE began the complete revision of Athens' law code. The fact that this process was not completed until 399 BCE indicates that the state

of confusion must have been great. In an attempt to achieve consistency, the revised law code mandated a distinction among laws, permanent rules of general application, and decrees (decisions made for a particular occasion). The Assembly continued to issue decrees on an ad hoc basis, whereas the making of laws was reserved for a special board of magistrates, the lawmakers (*nomothetai*).

Another consequence of Cleisthenes' democratic reforms in Athens was the transfer of all litigation from the magistrates to the Eliaia. One court, however, was unable to keep up with demand, and eventually the Eliaia was split into a number of courts staffed by juries. Every year, a list of 6,000 potential jurors was drawn by lot from all male citizens over 30 years old who had volunteered for jury duty. The jurors were then divided into juries as the need arose; the number of juries varied but typically numbered no more than 200 to hear specific cases. The allocation of individual jurors to cases was done by lot to prevent bribery or other judicial tampering. In order to ensure that the courts represented the entire citizen body, payment for jury service of two obols a day was instituted by Pericles as a way of encouraging the poor to serve. Even though Cleon later (425 BCE) increased the rate of pay to three obols a day, it was still less than half the wage that the average laborer could earn. The unintended effect of the payment for jury service was that it tended to attract the elderly poor, who had time to spare and did not need to support a family.

WASPS

In *Wasps*, Aristophanes satirizes the (probably exaggerated) eagerness of the old men of Athens to serve as jurors for the daily payment of three obols. In this passage, translated by David Barrett, one slave explains why his master has put his father under guard in the house:

“He’s what they call a *trailophile*, or litigious maniac—the worst case I’ve ever come across. What he’s addicted to is serving on juries, and he moans like anything if he can’t get a front seat at every trial. He never sleeps a wink at night—or if he does drop off, his dreams go fluttering round that water-clock till he wakes up again. He’s so used to clutching his voting pebble that he wakes up with his thumb and two fingers glued together, as though he’d been sprinkling incense for a new-moon sacrifice. Why, if he goes past Demos’ house and sees what someone’s written on the gatepost—you know the sort of thing: ‘Beautiful Demos, what charm you have got!’—he goes and writes underneath: ‘Beautiful urn, how I long for your slot!’ It’s true, honestly.

Once he complained that the cock was late calling him—and it was well before midnight! Said the retiring magistrates must have bribed it, because their accounts were coming up for review the next day. Oh, he did have it badly: as soon as supper was over he’d shout for his shoes, and off he’d go to the court, and sleep through the small hours at the head of the queue, clinging to the doorpost like a limpet. And mean! He’s so mean that he scratches the long line on his tablet every time they get a conviction—full damages; honestly; he comes home with enough wax under his fingernails to finish a beehive. He’s so afraid of running out of voting-pebbles that he keeps a whole beach of them inside the house here.”

Roman Law

Roman law developed out of the necessity to have a standard legal code from which to delineate prohibitions and regulations in early Roman society. Scholars trace the beginnings of Roman law to the issuance of the Twelve Tables in 451 BCE during the Conflict of the Orders (494–294 BCE), in which plebeians (commoners) demanded that laws be written down to ensure that abuses of their societal status on the part of patricians (elites) would be prosecuted. Distinctions between patricians and plebeians were taken into account, as were issues related to family law, the status of slaves, criminal offenses, and property. Much of the authority of early Roman law came not only through state enforcement of such laws but also through the prestige of specialists in legal scholarship who issued edicts. In later periods, edicts issued by the emperor or the Roman Senate would also carry binding legal authority. The extension of Roman law as Rome acquired territory through the Re-

publican (510–27 BCE) and Imperial (27 BCE–476 CE) periods brought a common codified legal system to much of the Mediterranean world. It is suggested by many scholars that Roman law is the basis of the legal systems of much of the Western world.

The Twelve Tables were the founding template of Roman law and continued to be relevant throughout the existence of the Roman state in its multiple political forms. Due to the constant strife between plebeians and patricians, a committee of ten patricians (the *decemviri*) was assigned to draft a set of laws to offer legal and social protections to both groups and also to delineate their specific rights. While scholars have been unable to decipher all the laws and their explicit meanings, they have been able to interpret many items that offer clues as to what the Romans deemed important in their society. Issues regarding legal procedures, answering court summons, debt, family relations (women and children), obligations between patricians and plebeians, property,

▶ ROMAN FAMILY LAW

Roman family relations were a pivotal part of early Roman law, as issues of inheritance, guardianship, and property were deemed important enough to enter into the Twelve Tables, the original law code of the Roman republic instituted in the years following the ejection of the Tarquins in 510 BCE.

“Table V

1. A dreadfully deformed child shall be quickly killed.
2. If a father sells his son three times, the son shall be free from his father.
3. As a man has provided in his will in regard to his money and the care of his property, so let it be binding. If he has no heir and dies intestate, let the nearest agnate (relative on father’s side) have the inheritance. If there is no agnate, let the members of his gens (family) have the inheritance.
4. If one is mad but has no guardian, the power over him and his money shall belong to his agnates and the members of his gens.
5. A child born after ten months since the father’s death will not be admitted into a legal inheritance.”

—Abraham O. Mendoza

“The Twelve Tables—451–450 BCE,” in *Primary Source Reader for World History*, Vol. 1, *To 1500*, edited by Elsa A. Nystrom (Belmont CA: Thomson-Wadsworth, 2006), 69.

inheritance, reciprocity, criminal offenses, slavery, and sentencing are addressed. Furthermore, prohibitions against capital offenses such as murder, social relations such as interclass marriage, or societal offenses such as the burning of corpses within the city are also addressed within the early rendering of the Twelve Tables.

As the complexity of Roman society changed over time due to territorial expansion, the granting of greater political rights for plebeians, and the inclusion of vast numbers of Roman citizens, new laws were enacted that reversed or contributed to the initial foundation of the Twelve Tables. In addition, legal edicts formed another important element in the formulation of Roman

law, as the legal profession became an important element within the expansive Roman state. Legal edicts, particularly during the republican period, came from praetors (elected magistrate) and were typically a general statement, principle, or prohibition. Issuing from elected officials representative of republican institutions, these laws reflected the societal belief that such individuals held the interests of Roman society supreme. However, in the Imperial period, legal edicts were issued at the discretion of emperors, sometimes as an example of their arbitrary whim, illustrating the changing conceptions of law under the empire as distinct from the republic. Nonetheless, during the Principate the profession of the jurist came to have a significant role in the issuance of laws. Jurists, who were highly trained legal scholars, were typically aspiring politicians who were well versed in law, legal procedures, and rhetoric. Jurists were primarily responsible for writing on law, its meaning, and its interpretations. This allowed for the creation of a set of standards and precedence to be used for case law throughout the empire.

Ancient Chinese Law, 1000 BCE–220 CE

When the Zhou dynasty (1040–256 BCE) was established, the leaders employed two concepts to justify their reign that had been developed during the previous Shang dynasty: the righteous or just war and the mandate of heaven (*tianming*). Subsequent dynasties followed this example.

The Zhou dynasty governed with an elaborate administrative system and a complex military organization. Laws were developed to manage them. The king or high officials served as judges, issuing verdicts against subordinate officials for dereliction of duty and against the

common people for criminal acts. Evidence concerning the legal system and its statutes is light. Extant sources, however, reveal the existence of both tort and property cases. As the technology improved and the economy developed, the frequency of property cases increased. The Zhou primarily maintained social order, political control, and diplomatic relations through the harmony of ritual (*li*) rather than the rule of law that dominated Greco-Roman (and later Western) cultures. The hallmark contribution of Confucius (Kongzi, d. 479 BCE) and his disciples was the codification of the proper forms of deportment and virtuous action under the practices of ritual, clan morality, and family values that regulated almost every form of human behavior from simple gestures, such as bowing, to national order and international diplomacy. Ritual was the Chinese panacea for all personal, social, and national problems or disagreements. Laws to control, sanction, permit, or punish behavior were primarily employed in the government administration and military. As Zhou culture changed and trade prospered, the mercantile class developed, gaining social status and some political influence. The system of ritual and the laws were modified to accommodate the needs of the state, the king, and the officials.

When the Zhou dynasty was founded, the king enfeoffed his relatives and supporters. After the Zhou capital was moved toward the east (770 BCE), the feudal lords gained power. During the Spring and Autumn period (772–481 BCE) the number of small states had grown, and the most powerful among the feudal lords gained prominence, declaring themselves to be lord protectors (*ba*) of the Zhou house. By the Warring States period (403–221 BCE) the feudal lords had declared themselves to be kings, and under the protection of the concepts of just war and the mandate of heaven they vied for political and military power. The geopolitical sphere extended south of the Yangzi River. After the sixth century BCE the literary references to legal codes increase greatly. The *Book of Documents* (*Shujing*) and the *Spring and Autumn Annals* (*Chunqiu*) praise the tradition of ancient laws established by the sage kings. The Confucian respect for and appeal to the past created a histori-

cal tradition of legal and ritual precedent. In the *Zuo Zhuan* commentary to the *Chunqiu*, there are records of speeches admonishing rulers to reform their governments and laws. Later the Legalists (Fajia) became the advocates for legal reform (*bianfa*). In 536 Zi Chan in the state of Zheng had the penal law cast onto bronze tripods. In 621 Fan Xuanzi reformed the laws of Duke Wen during the reign of Duke Xiang in the state of Jin. These laws were revised and finally cast onto a tripod in 513. Subsequently, Deng Xizi's *Bamboo Penal Code* and Li Kui's *Classic of Law*, which drew on the laws of the various states, were published.

In 256 BCE the Qin house vanquished the Zhou, ending the dynasty. The state of Qin eventually defeated the remaining kingdoms and unified the empire in 221 BCE. To manage the newly formed multiethnic empire, the Qin established ritual and legal codes. The complete Qin legal code has not yet been excavated. The evidence shows that the Qin code was sophisticated and extensive. After the short-lived Qin dynasty (221–206 BCE), the Han dynasty (206 BCE–220 CE) was established. The Han legal code has not survived intact either. The surviving evidence reveals that the Han code was even more extensive than the Qin code. Because the legal codes contained harsh punishments for dereliction of duty, criminal acts, and treason, they probably were among the first documents to be destroyed during the collapse of the dynasties. The Qin and Han legal systems were complicated, with various bureaucratic layers and offices. There was a great deal of concern about documenting the investigation and the trial. Beatings and coercion were employed to obtain the facts or a confession. The texts claim that the best investigation discovered the facts of a case without harming the witnesses. The statutes focused primarily on public law. The Qin and Han statutes emphasized legal duties. The concept of legal rights is absent. They practiced a privileged legal system in that people with high social status were given lighter sentences than those with low status. The Qin and Han legal codes and practices established the patterns and precedent that all subsequent dynasties employed to maintain social order.

■ Introduction: Gender

There is substantial evidence for a diverse variety of understandings of gender within the period from 1000 BCE to 300 CE. Historians are only now beginning to grapple with the true complexity of understanding ancient conceptions of gender that in many ways do not neatly align with our current experiences of gender. As most scholars understand gender, it is different from sex, which is a biological distinction between male and female. Gender is the cultural and social distinction, which is related to sex but is not necessarily divided along the same bifurcated lines.

This section of the encyclopedia attempts to identify these different conceptions of gender found throughout the world from 1000 BCE to 300 CE. In some cases, as in Greece and Rome, these differences were explicitly discussed by ancient authors, and thus we are able to come to more concrete conclusions. In other instances, as in the case of the people of the Americas, historians must use indirect evidence, such as art-historical gender depictions, in order to reconstruct ancient gender.

—Kevin M. McGeough

Concepts of Gender, Gender Distinctions, and Roles in the Ancient Near East

The concept of gender, as interpreted by the Near Eastern peoples of antiquity, assigned specific roles to men and women within both the household and the public sphere within their respective

Mesopotamian societies (which varied over time and space). Typically, these roles were shaped by both societal expectations and religion. Gender roles and relations shaped the interactions that men and women had with each other, within their families, and with greater Mesopotamian society. It also marked their specific life trajectories as daughters and sons and subsequently as wives and husbands and mothers and fathers.

As children, both boys and girls were socialized by their parents for their specific gender roles in later life. Typically, most children would learn from their parents within the household. Boys were expected to adapt themselves for later life by acquiring an education or an apprenticeship in order to later pursue a suitable profession in adulthood. Girls acquired the skills of running a household from their mothers among other skills that would be deemed valuable later in life as they became wives and mothers. Young women were considered ready for marriage by their teens. In contrast, young men would marry later, typically in their mid to late twenties. Marriage was arranged by the fathers of households, taking into consideration political and economic factors that would benefit the family. An engagement would be marked by a verbal contract and an exchange of bridewealth (for the bride's family) and dowry (the bride's family's contribution to the marriage).

Upon marriage, a woman and her dowry became part of her husband's household. While monogamy was considered ideal, extramarital affairs, polygamy, and concubinage did occur. Divorce laws varied from time to time in ancient Mesopotamia, with certain stipulations desig-

nated on both men and women, often granting them either equal status or higher regard toward the men at the expense of their wives. However, if divorce occurred after a woman had given birth to sons, the husband would incur a significant financial penalty, such as the loss of his house and property. Women were scrutinized before divorce proceedings, taking note of a woman's moral behavior before a divorce would be granted. Upon divorce, she could retain her dowry and had the right to remarry.

Husbands and wives had differing roles within the household. While men were expected to make a living to bring sustenance into the home, women also contributed to the running of the household in the absence of the husband. In the running of day-to-day business affairs, the wives of skilled artisans and merchants would handle daily transactions at the behest of their husbands. In large households, wives were in charge of conducting the affairs of the home by supervising servants, apprentices, and other members of the household. As mothers, women were primarily in charge of the rearing and education of the children. Men were relegated to roles in the political sphere and in military affairs as part of their responsibility to the Mesopotamian state. However, women, through their husbands, possessed a level of informal and indirect political power, particularly aristocratic and elite women.

Concepts of Gender Encoded in the Development of Kouros and Kore Statues

During the seventh century BCE, the Greeks learned the art of carving sculpture in the round from the Near East. Large sculpture was presum-

SEXUALITY AND GENDER IN THE ANCIENT NEAR EAST

While deemed inappropriate and immoral, premarital sex and promiscuity were common in ancient Mesopotamia. Marriage was still expected to be the norm for both women and men. Prostitution was a common practice in ancient Mesopotamia, practiced in certain areas around the city walls or taverns, as long as it did not infringe on or threaten marriage. Sexuality was an accepted part of life in these societies, playing a function in the quotidian existence of the people not only for purposes of procreation but also for recreation and pleasure.

—Abraham O. Mendoza

ably attempted earlier in wood but does not survive well in the archaeological record. The first Greek stone sculptures were almost exclusively of two types: the kouros (meaning “boy”), a nude youth, and the kore (“girl”), a well-dressed young lady. Both of these types continued to develop throughout the sixth century BCE. Their poses were selected due to the influence of Egyptian stone sculptures, and they were rendered in the style of the artwork of Southwest Asia. Yet they were infused with a uniquely Greek set of aesthetic values. Used both as dedications in sanctuaries and as grave markers, these monuments were a way in which members of the aristocracies of the Greek city-states could display their ideals for both men and women. A most prized quality for both genders was that of youth, so both kouros and kore statues always depicted young people. Kouros were fit and vigorous as well as clean shaven, denoting unmarried status. These males were also shown in the nude, implying that the figures were engaging in athletics, which Greek men performed naked.

Korai were young women, ideals of feminine beauty. They were elegantly dressed in fine clothes, and they often daintily hold up their long skirts showing that they were accustomed to wearing fancy dresses. The clothing styles on korai changed often, reflecting transformations in fashion. Kore statues often had attachments in metal or carved representations of jewelry,

► THE KORE OF PHRASIKLEIA AND KOUROS FROM MERENDA

This pair of statues from the sixth century BCE was used as grave markers in a cemetery near Athens. They were found together and probably were sculpted by the same artist, Ariston of Paros; however, only the kore statue is signed. The female statue is identified as a memorial for Phrasikleia, a girl who died before she was married. We lack the base for the male, but many statues of this type were grave monuments for unmarried men. In overall appearance and hair-styles the two figures are so similar that they could be twins. However, the artist paid a great deal of attention to the dress of the female statue, showing her in a long gown and jewelry. Meanwhile, the male is a fit athlete, and his anatomy was shown in close detail. It was important in permanent memorials to show each of the figures at the moment in their lives when they were at the height of their beauty.

—Angela Murock Hussein

Kore of Phrasikleia and Kouros from Merenda, by Ariston of Paros. (Rene Mattes)

implying the wealth of the girls' families. Well-dressed women implied that they were from prosperous families and were well cared for. They also often held fruit or flowers, denoting the fertility and potential value of these nubile women as brides. Both kouroi and korai were shown with long elaborate hairstyles, which identified them as members of the wealthy class that did not have to do physical labor. The statues may also have been painted with different skin tones, darker for males and lighter for females. Men were expected to be robust and to

spend much of their time outside, while women were expected more often to remain indoors.

Etruscan Women

The Etruscans were a people who emerged in central Italy sometime before 800 BCE and who developed an advanced civilization that reached its height in the seventh and sixth centuries BCE. Scholars still argue over the origins of these people—some claim they came from the east, and others suggest that they developed from the indigenous peoples of Italy. Regardless of their origin, scholars agree that they produced a society that was highly influential, for by the sixth century BCE they ruled over an extended area that included the early settlers of Rome. They were a great trading people and competed with the Greeks and Carthaginians for the wealthy trade of the western Mediterranean. The Etruscans also were master builders, and they were skilled at reading omens; subsequent Roman society was to take many of these Etruscan developments and make them their own. In one area, however, the Etruscans contributed little to the rest of the Mediterranean world—their treatment of women. The Etruscan women took a strikingly public role, which shocked the Greeks and Romans who observed it.

It is difficult for historians to get a full picture of Etruscan society because we cannot read their language. Therefore, we must use only others' accounts of their customs, which are highly biased, and archaeological evidence, which fortunately is very rich. The most shocking thing that the Greek authors observed was that men and women dined together. Aristotle said that Etruscan husbands and wives reclined together at dinner (instead of sitting in chairs, ancient Mediterranean people reclined on couches around a table). In Greek society, the only women who joined men at banquets were prostitutes, so it seemed to the Greeks that all Etruscan women were therefore sexually free.

The longest description of the Etruscans comes from the fourth-century Greek historian

THEOPOMPUS ON ETRUSCAN WOMEN

Although no literature survives from Etruscan civilization itself, later Roman sources, as well as Greek historians, preserve legends of the vanished Etruscan culture of the seventh and sixth centuries BCE as well as of the licentious behavior of its women. Theopompus of Chios wrote as follows in the forty-third book of his *Histories*:

“Sharing wives is an established Etruscan custom. Etruscan women take particular care of their bodies and exercise often, sometimes along with the men, and sometimes by themselves. It is not a disgrace for them to be seen naked. Further, they dine, not with their own husbands, but with any men who happen to be present, and they pledge with wine any whom they wish. They are also expert drinkers and are very good looking.”

Such literary accounts are probably highly exaggerated, and are in addition meant to be a systematic inversion of Greek culture and the restricted sexuality and license of Greek women.

—Kelly Olson

Theopompus. He said the Etruscan women were “extraordinarily pleasure-loving,” for they dined not only with their husbands, but with other men. Furthermore, they had free sexual lives: “It is not shame for the Etruscans to be seen having sexual experiences . . . for this too is normal: it is the local custom there.” He goes on to say that people shamelessly call sexual intercourse by its name if telling someone the master is busy making love.

Archaeologists are able to confirm some of these accusations on the basis of rich tomb paintings and sculptures in the Etruscan burial vaults. In the wall painting of a banqueting scene, Etruscan women are shown enjoying a dinner party in the company of men. So it appears that women did join men in public in a way that respectable Greek and early Roman women did not. Furthermore, there are paintings of women joining men to watch games and contests in public. The clothing of the women in paintings and sculptures also suggests a public life for women, for there

were many more shown in shoes and mantles—public attire—than were present in comparable Greek portrayals.

Etruscan art also indicates affectionate family relationships. Most show men and women reclining together on a couch, with their arms affectionately around each other. One even shows the married couple naked together on their marriage bed. The Greeks would have found such a portrayal shocking, for although men were frequently nude, respectable women—even in a marriage bed—were not. It may be that such figures offer evidence to confirm the Greek historian's assessment that the Etruscans—men and women—were comfortable with their sexuality.

Theopompus also commented on the Etruscans' affection for their children. In contrast to Greece and Rome, where the father could determine whether the child would be raised or exposed to die, the Greek historian noted that the Etruscans raised all the children who were born, even if they did not know who the father was. The only independent confirmation we have of differing attitudes toward children is the presence of small statues of women nursing their babies. These statues are unique in the ancient world—this was not an artistic theme for the Greeks. Some scholars suggest that these figures indicate that Etruscan women personally raised their babies.

The Roman sources imply that Etruscan women of the royal family had a strong role in governing the society. According to one legend, an ambitious Etruscan couple arrived in Rome in about 630 BCE. As the man and his wife looked down from their wagon on the city that was to be their new home, an eagle came down and plucked the man's hat off. It then swooped back down and replaced the hat. The woman—who like most Etruscans was skilled at reading omens—joyfully embraced her husband, for she explained that this was a sign that he would be king. The prophecy came true, and Lucius Tarquin became king of Rome. His wife was the powerful Etruscan queen Tanaquil. This story repeated the reputation Etruscan women had for prophecy and reading omens, which was continued throughout their history.

If Etruscan women reputedly had more freedom than women in the rest of the Mediterra-

nean world, they also had the same opportunities as men for political intrigue and cruelty. The Roman historian Livy tells of an Etruscan queen named Tullia who violated the laws of family to forward her ambitions. According to Livy, the Etruscan princess persuaded her husband to kill her own father so they could rule, and she brazenly rode in an open carriage to the forum to see the results. Her husband, Tarquin, told her to go home, as the crowd might be dangerous. As she was leaving, her driver stopped the cart, for her father's mutilated body lay in their path. The "crazed woman" drove the carriage over her father's body so that blood from the corpse splattered her clothing. This story told by a Roman recounted the fall of the Etruscan monarchy, which restored a society in which women did not have the freedom they had under the Etruscans. Did he exaggerate the woman's cruelty to prove that the Etruscan way was corrupt? Perhaps. It would be centuries before respectable women again would experience the public life enjoyed by the Etruscan women of the ancient world.

Concepts of Gender, Gender Distinctions, and Roles in Rome

In constructing gender identities, ancient Romans considered a variety of factors, including sex, social status, legal status, marital status, wealth, age, and sexual behavior. As a result, there were not simply the two gender distinctions of man and woman but a multiplicity of dif-

➤ VESTAL VIRGINS

The Vestal Virgins were essential to the Roman religion, as their rites ensured the continued prosperity of the Roman state. In addition to participating in certain rituals during the year, the Vestals were chiefly responsible for maintaining the goddess Vesta's fire and guarding the sacred storehouse where Rome kept important objects that it believed were integral to the preservation of its society. Because most religious positions were reserved for men, it is significant that the Vestal Virgins were six female priestesses who were selected between the ages of 8 and 10 to serve for at least 30 years.

As Robin Wildfang argues, the Vestal Virgins held a unique status. Beginning with their initiation, the Vestals occupied a liminal, or threshold, position between the two respectable statuses for female citizens: virginal unmarried women and chaste married women. To emphasize this publicly, the Vestals wore the hairstyles of brides along with the clothing of wives. In this position, the Vestals were not bound to familial cults, as were virgins and wives, but they were bound to the state. It is perhaps for this reason that the punishment for Vestals

This nineteenth-century engraving, based on a painting by Hector Le Roux, depicts the school of Vestal Virgins of Rome. The Vestal Virgins tended the eternal flame of Vesta. The priestesses were recruited as children and made a commitment of 30 years, during which they must remain celibate, and after which they were free to marry. (Ridpath, John Clark. Ridpath's History of the World, 1901)

who failed in their duty by losing their virginity was especially harsh; they were buried alive.

—Kate McGrath

ferent possible genders. Each of these conceptions of gender conferred unique understandings of the individual's function and status in Roman society. Underlying all of these conceptions of gender, however, was the importance of the Roman virtue of *virtus* ("manliness"). In the early Roman republic, *virtus* described the courage and military valor of Roman male citizens. Even when it later evolved into meaning something closer to our own use of the term "virtue," scholars, such as McDonnell, argue that it still retained its classical association with virility and masculinity. Moreover, the Romans, drawing on the biological teachings of the Greeks that women were imperfect—and even deformed—men, associated femininity with passivity and thus the antithesis of *virtus*. As a result, the ideal Roman citizen continued to be defined as a man.

Such idealization perhaps accounts for the tremendous power held by certain men. During the republic, Roman male heads of households, the *paterfamilias*, commanded absolute author-

ity over their families by holding the power of life or death. They also held control over all the family's property, and their permission was needed in order for members of the family to marry or divorce. This power was so expansive, in fact, that the *paterfamilias* could initiate the divorces of his children and even sell them into slavery. When the *paterfamilias* died, his sons would become the *paterfamilias* of their own households. Although Roman society recognized the adulthood of male citizens at the age of 17 in a religious ritual, called the *Liberalia*, in which the new adult man formally put on his citizen toga, a man was still bound to his father's authority, like his sisters, until his father's death.

In contrast to male citizens, male slaves could never become fully adult men because of their low servile status. They were instead considered to be permanent *pueri*, or boys, who were thus incapable of exhibiting masculinity. Male slaves' legal status as property coupled with the construction of their gender as

effeminate and passive influenced their relationships with male citizens. As with female slaves, Roman men considered their male slaves to be sexually available for their pleasure. While some scholars have defined such male citizens as homosexual, many argue that it is an anachronistic label. Roman men did not conceptualize their sexual behavior in terms of sexual orientation; rather, they were concerned with who was the passive or active sexual partner in discrete sexual acts. As long as they were the penetrators of a passive partner, either a woman or a male slave, there was no risk to their masculinity and thus no need to express a sexual preference for either men or women or both.

Likewise, the patriarchal nature of Roman society greatly influenced the construction of female status. Roman female citizens could occupy one of two socially acceptable categories: *virgines* (“virgins”) or *matronae* (“wives”). Virgins were the daughters of citizens who conformed to social norms in regard to virtue and celibacy before their marriage, while wives were those who continued to exhibit appropriate virtue by remaining faithful to their spouses. Both categories demanded that women remain sexually virtuous in order to be viewed as respectable. The most honorable women were the *univira*, or those who had only ever been married once. This is noteworthy, because many wives remarried after divorce or widowhood. For all wives, chastity was so important that they were expected to display their sexual virtue, known as *prudicitia*, publicly so as to bring honor to their husbands by thwarting any suspicions of adultery. They did so by dressing appropriately, conducting themselves appropriately (keeping their eyes averted in public, refraining from talking excessively with other men), and participating in religious rites for chaste wives.

In addition to being sexually restrained by Roman norms of virtue, Roman women were often constrained legally as well. Most Roman women were under the authority of a man, either their husbands or their fathers. In the republic, the common form of marriage involved the transfer of authority from the father to the husband. This is typically referred to as a *manus* (“hand”) marriage, because the groom takes the hand of the bride and hence jurisdiction over

her, from the bride’s father. By the time of the Roman empire, however, most brides were not transferred to the authority of their husband but instead remained under the authority of their father and thus remained part of their birth families. Such daughters would have been expected to act as intermediaries between their birth families and their new husband’s families. Even at the death of their husbands or fathers, most wives remained under male supervision because they were required to have tutors, or guardians, to conduct economic or legal transactions. While these guardians maintained the image of patriarchal authority, they did not often wield much influence over the lives of elite widows. Under Augustus Caesar, female citizens who had three children and freed slave-women who had four children were rewarded with emancipation from their tutors. Even before this change, however, elite women were able to exercise considerable financial control over their assets, with women frequently being granted the right to choose their own tutors and even being able to appeal the decisions of their tutors.

A similar experience was possible for lower-status women, whose economic roles were not always distinguishable from those of men. Evidence shows that these women regularly worked as artisans, shopkeepers, grocers, etc., alongside their husbands, fathers, or sons or independently as widows. Also, all Roman women were charged with the management of the household and its expenses. This involved monitoring consumption and servants. All of this suggests that while Roman women may have been constrained by certain social and legal conceptions of their gender, nonetheless there remained a considerable amount of freedom in the negotiation of their economic lives.

Hellenistic Queens and Roman Matrons

The rise of the Hellenistic queens and Roman matrons eased social restrictions on women. They used wealth to gain access to male social circles. The economic collapse that began in the third century CE, however, led to the loss of women's rights.

The role of women in Classical Greece was extremely restricted. Then, beginning in the fourth century BCE, several powerful royal women changed their contemporaries' notions about women's roles in society. While most Hellenistic women still led cloistered lives, these queens broadened the social possibilities for all women, in part by taking on the attributes of men. For instance, Eurydice, Philip II of Macedon's daughter, wore armor when she met Olympias, Alexander the Great's mother, on the battlefield.

Coinage, inscriptions, and records on papyrus give us details of several women's lives. Contemporary writers generally presented negative portraits of powerful women, largely because they behaved against their gender stereotype. Unpopular sons also resulted in the vilification of the mother, as was the case with Tiberius's mother, Livia, and Commodus's mother, Faustina the Younger.

The Hellenistic queens rarely held power in their own right. Arsinoe II married her brother, Ptolemy II of Egypt, and used war and murder as well as her beauty and administrative skills to maintain her position. Cleopatra VII, the most infamous of the Hellenistic queens, married her brother, but contemporaries considered her to be the real ruler of Egypt. The Roman matrons never held power directly, but they were very

> EUMACHIA

Some of what we know about women's occupations and influence comes from their tombs. One of the best examples is that of Eumachia of Pompeii. Although she came from a family of brick makers, she was a public priestess who used her inheritance and business skills to become the patroness of the fullers of Pompeii, who erected a statue to her. From her own funds Eumachia built a porch, a colonnade, a covered passage, and a tomb for her household. She secured an excellent marriage for herself, and she sponsored her son's political activities, possibly in imitation of the empress Livia.

—Linda Malcor

much the power behind the men. For instance, Hadrian was required to marry Sabina, Trajan's great-niece, in order to secure his throne.

As royal women expanded their power, social roles widened for other women. An increasing number of them earned citizenship, held property, and funded public works projects. These women studied with philosophers, held minor government positions, and enjoyed better legal rights, such as the ability for women without male protectors to represent themselves in legal matters.

The Roman matrons' greater wealth accounted in part for the greater social freedom they enjoyed than their Greek counterparts. While Hellenistic queens apparently did not take lovers, literary sources suggest that Roman matrons enjoyed sexual freedom akin to that of their husbands. The virtuous Cornelia, Scipio Africanus's daughter and mother of the Gracchi, gave birth to 12 children before she engaged in activities formerly reserved for men, and her overzealousness in this traditionally female role may have been what spared her the criticism aimed at other Roman matrons.

As with the Hellenistic queens, the Roman matrons gained political power when their men were at war. The high divorce rate, a declining birthrate, and a scarcity of women in the upper classes, partially due to mortality during childbirth, inspired Augustan laws that enabled

women in general to enjoy greater control over their own lives. Raising children was also a path to political power. Octavia, Antony's second wife and the sister of Augustus, secured her place in society by raising her own children as well as most of Antony's from his two other marriages, to Fulvia and Cleopatra.

As the empire experienced difficulties in the third century CE, many women's rights were taken away, not to be recovered for many centuries. The great queens of later years, such as Eleanor of Aquitaine and Victoria of the United Kingdom, owed a great deal to the Hellenistic queens and Roman matrons.

Women in Rome

It would be impossible to describe all of the roles that were available to women in ancient Rome. But an interesting avenue of research is to study the kinds of roles that were glorified in literature and art. But as with all people, it was possible to fill many roles and have many identities. The average modern individual plays various roles throughout a lifetime. It should be assumed that the ancient world had similar levels of complexity regarding the roles women could play.

One of the primary roles associated with women in Roman times was that of mother. This is not surprising; it is a biological fact of human existence. But what makes this category interesting in Roman times is the centrality of the mother in Roman culture. A woman's virtue was intrinsically linked to her reproductive skills and to her responsibilities as a mother. A common

notion in scholarship is that women's activities were closely guarded to ensure the paternity of their children, because in antiquity, fatherhood could not be proven scientifically. One of the best sources for these attitudes toward women is mortuary monuments. One of the glowing qualities most often commemorated in funerary inscriptions was the description of the woman as an ideal mother.

Funerary inscriptions also tell much about another role of women—that of wife. Because eulogies tended to describe positive qualities only, the descriptions in ancient eulogies (while not necessarily true of the actual person) were indicative of wider cultural values. The highest virtue that a Roman woman could possess was *pudicitia*, devotion to her husband. For all Roman women, with the exception of the Vestal Virgins, it was expected that they should have a husband. A woman without a husband (unless widowed) was seen as aberrant, and the fringe position of prostitutes within Roman society attests to this.

There were many roles that women could play in religious life. The Vestal Virgins were among the most powerful cultic officials in Rome. Likewise, the wife of the *rex sacorum* (the religious official who acted on behalf of the king) played an important role in Roman religious ceremony. There were deities and festivals that were exclusively the purview of women. The *pax deorum* was held twice every year. This was a feast only for married women, held in honor of the goddess Bona Dea.

One of the problems with the study of Roman women is that most of the available evidence has been distorted through male eyes. Almost all of the texts are from a male perspective, and artistic evidence is likely just as phallogocentric. This makes it imperative to understand the social beliefs people held about women in order to make use of these sources. If the biases of one's sources are known, there is a much better chance of understanding why a given source says what it does.

One of the traditional male views of women in Roman times was that they required male guardianship in most of life's stages. Before marriage, women were seen in relation to their fathers, with the father acting as the sole guardian.

From the father's house, the normative next step for a Roman woman was marriage and the guardianship of her husband. It certainly seems that in an ideal biography (from a Roman male perspective), a woman was in a man's care at all stages in her life. Even in the absence of a father or husband (through death, for example), there was usually a male who could step in as *paterfamilias*, from an ideal perspective. In actual practice, however, the constancy of male guardianship would have differed considerably in every situation.

The roles of women in the myths of the foundation of Rome are compelling. Consider the story of the rape of the Sabines. From this myth, Roman society is cast as initially completely composed of males. These males (in the male-only society) seize and rape a group of women from another city. In antiquity, the emphasis on the rape aspect did not cast the males in a negative light, but rather emphasized the sexual purity and virtue of the female ancestors of the Romans. Likewise, the rape of Lucretia demonstrates the qualities of a virtuous woman in terms of sexual chastity. On the other hand, women are seen very negatively in the story of the sacking of the Capitoline Hill by the Sabines. A woman, according to Livy, showed the Sabines a secret route in exchange for payment.

Women were not allowed to vote, nor were they allowed to run for public office. Although they could participate in public gatherings, their direct participation in civic government was barred. This meant that any influence on government activity during the republican period was indirect, and as such, is very difficult for historians to trace. In the Imperial period, the status of women in regard to political life did not change. But historians are better able to trace the effect of some notable women on political life. These women were people who were close to the emperor. Because of the emperor's power, anyone close enough to personally influence him could also influence public life.

In Roman literature, the influence of women on male politicians was not looked upon favorably. Women who attempted to act in the public sphere were described as liars, overemotional, and unable to control their desire or temper. As a means of discrediting a male politician, accusa-

➤ WOMEN IN THE PUBLIC SPHERE

For all who argue for the cultural superiority of the Greeks over the Romans, the position of women in the public sphere is perhaps the best counterargument. In Greek society, women were curtailed from participation in public life to an extreme degree. Although in actual practice it may not have been the case, the ideal Greek woman never left the house. This was certainly not the situation for Roman women, who were allowed a significantly higher degree of civil liberty than most ancient women. Women were a constant presence in Roman public. They were not restricted in their ability to move around the city, and they participated in spectacles, baths, and other public activities.

There are also recorded instances of women acting in the public sphere as a collective. One occasion came as a response to sumptuary laws passed in the wake of the second Punic War. The *lex oppia* (opulence laws) limited the amount of gold women were allowed to possess. In 195 BCE, women demonstrated in the streets to have this law repealed, and it was. This event is known from the writings of Cato the Elder, who warned about the dire consequences of women who possess too much wealth. There are other examples of women acting as a group. In 309 BCE, women were said to have gathered 1,000 pounds of gold to bribe invaders to leave the city. And supposedly, under Emperor Elagabalus, a women's Senate was formed to create a code of female etiquette.

—Kevin M. McGeough

tions about the influence of his wife could be levied. More prominent in Roman history than the wives of politicians were the mothers of politicians. There was a considerable degree of variation in the influence that mothers had over male political actors. On the one hand, there was the influence the mother had as the earliest role model for the child, an influence that should not be ignored, but one that is more difficult to see historically. On the other hand, there are the infamous mothers (e.g., Agrippina, mother of Nero) who wielded considerable influence at court.

The stories about barbarian women provide very interesting insights into Roman conceptions of gender and otherness. Boudicca, who lived c.

26–60 CE, was the queen of the Iceni tribe, a Celtic tribe in Britain. She led a revolt against the Romans and had many military victories, but was eventually defeated. Queen Zenobia of Palmyra, who lived around 260 CE, also went to war against Rome, but was eventually defeated. The Roman descriptions of these women are very interesting. Both were described in a virtuous light, and they seem to have commanded the respect of the Romans. On the other hand, there is a very romanticized otherness about these women and their people. That these barbarians would allow themselves to be led by women was more evidence of their savagery.

Gender Distinction in Early Christianity

During the first five centuries of Christianity, the Catholic Church of the West invented a gender distinction in Christian leaders' consistent struggles against the Roman imperial authorities and their complicated interactions with the Jewish faith and other pagan religions in and outside the empire. This culturally constructed distinction based on the doctrine of Original Sin degraded women morally, and while being transformed into institutionalized powers by the leadership of the Church throughout the Middle Ages, it resulted in alienating women from their normal social functions and political participation in the traditional West.

In the early centuries of Christianity the stories of what Jesus did and said were circulated among peoples under Roman imperial dominance and interacted with diverse pagan religious traditions. Those traditions were, in general, socially and culturally patriarchic, view-

ing women as a weaker gender than men, practicing taboos against women's participation in official religious rituals during their menstrual periods, and limiting women's functions more or less within domestic spaces. These misconstrued ideas and discriminative practices against women were founded on a superstitious understanding of women's physiology and served various sociological purposes of agrarian societies. However suppressive the ideas and practices were, the militaristic Romans never stopped venerating the duties of the Vestal Virgins by tending either the flames of their household's hearths or of the hearth in the House of Vesta to ensure the prosperities of both their families and Rome as a whole. Women all over the empire continued to demonstrate their devotion to female deities such as Isis in Egypt and North Africa, where unique religious rites and celebrations were closely linked to crucial life experiences, such as happy marriage, fertility, safe childbirth, health of family members, and deaths. Although different norms reflected different religious ethics and social expectations were in place to marginalize women's roles in public spaces, women's voices and participation in public life were never completely suppressed.

The new Christian faith offered women a liberating inspiration because the recorded acts of Jesus did not discriminate against anyone on the basis of ethnicity, social status, or gender. The early Christian movements eventually attracted women's conversions and encouraged them to spread the faith to other women, mothers to their children, wives to their husbands. The early Gospels, including the ones that were not later included in the New Testament, bore witnesses to Mary (the mother of Jesus), Mary Magdalene, and a few other women as the most humble and faithful followers of Jesus and the most patient and effective prophets of his messages. Moreover, in his letter to the Romans, Paul mentioned about a dozen female converts and activists. Among them, he showed his intention to give a certain female deacon Phoebe "a welcome worthy of God's holy people" and thanked her for "the help of many people, including myself" (Romans 16:1–2). Most recent historical researches have acknowledged that quite a few female prophets, patrons, teachers,

and missionaries are recorded in the New Testament and suggest that some of them were ordained to fulfill a variety of religious duties in the same manner as their male counterparts during the time period when church structure was not formally established.

In the second and third centuries charismatic leaders, activists, and scholars of Christian movements were able to gradually organize themselves and build up a consensus on the components of the New Testament. In denouncing the Roman earthly kingdom and popularizing a new universal covenant with God, they began to provide their faithful followers with coherent norms to be observed on a range of theological and moral issues against the pollutions of external pagan teachings and philosophical insights. Meanwhile, they also began to fight against the internal dissents, or heretics, in their attempt to establish Christian orthodoxy. Moral purity and ethical disciplines were therefore pushed to the forefront of their agenda. At the turn of the third century Tertullian (ca. 155–222), a convert to Christianity in North Africa, publicized a series of treatises in his battle against the movement of Montanist apocalypse led by two women, which provides us with some insights into the moral concerns of the Christian thinkers of the time. On the one hand, he relentlessly advocated monogamy and blamed both men and women for their promiscuous affairs out of wedlock. In this respect, the upcoming Christian canons of marriage would become very distinguishable from marriage codes of other religions. At the same time, while affirming the virtues of virginity, chastity, modesty, and other ascetic values of his cherished faith, he aggressively accused each and every woman of being “Eve” and the “devil’s gateway.” His condemnation went so far as to argue that on account of women’s desertion of divine law, they ought to be responsible for the death of Jesus and the fall of men, who were created according to God’s image. Tertullian’s rhetoric translated the Greek myth of Pandora, the first woman as the bringer of evil, from a mythic allegory to a theory and planted the roots of Original Sin, which is to be constructed as a misogynic doctrine of Christianity.

Emperor Constantine changed the destiny of Christianity through his personal conversion in

➤ TERTULLIAN, “ON FEMALE DRESS”

“Do you know that you are each an Eve? The sentence of God on this sex of yours lives in this age; the guilt must of necessity live too. You are the devil’s gateway; you are the unsealer of that forbidden tree; you are the first deserter of the divine law; you are she who persuaded him whom devil was not valiant enough to attack. You so carelessly destroyed man, God’s image. On account of your desert, even the Son of God had to die.”

the early fourth century, which was followed by Christianity being declared as the imperial religion at the end of the century. The Christian leaders and thinkers were therefore no longer passive defenders of their faith for its survival but became determined and enthusiastic engineers for reconstructing the social and moral orders of the Roman empire, which was suffering from internal decay and external intrusions of Germanic peoples. In the whole empire, women began to be barred from priestly activities as the fourth-century Apostolic Constitution had declared. In the western part of the empire, the ideas of integrity and universality motivated bishops in Rome to patronize more aggressive intellectuals to formulate doctrines and take more assertive actions to change the religious attitudes and ethic norms of the people, including Germanic peoples migrating into the empire. To St. Ambrose (ca. 338–397), the Church should preserve its doctrines intact and prevent itself from the penetrations of false ideas by the “barbarians.” He reinvented and theorized the virginity and purity of Mary, the mother of Jesus, to protect the integrity of the Church. St. Augustine (354–430), in analyzing the fall of Rome, traced the fallibility of all humans to the original cause of Eve’s seductive persuasion of Adam to

eat the apple. Eve poisoned Adam, and Adam passed in turn the inherited guilt to all of his descendants through sexual acts. Therefore, marital sexual acts with the purpose of reproducing children were necessary, but irrational desires for sexual pleasure, which he termed “concupiscence,” ought to be condemned because they prevented humans from loving God and holding, contemplating, and enjoying happiness in God. This reasoning appears to echo Tertullian’s rhetoric, but St. Augustine aimed less to repudiate any specific heresies of his time than to invent and elaborate a general and intrinsic moral flaw of the female gender and therefore, founded the universal doctrine of Original Sin. This idea was quickly adopted by the Catholic Church as a very fundamental terminology in its constructions of theological doctrines and canon laws through its successive campaigns to denigrate sexuality in general and degrade women specifically.

The total exclusion of women from priestly missions and the theological doctrine of Original Sin constituted two of the most crucial components of the female gender distinction of the Catholic culture. It was excessive, because no other peoples in the Roman world, including the Orthodox Christians, cast such a catastrophic light on Eve and thus condemned women by the misogynic and general term of Original Sin. It was also ironic, because women living with such negative and pervasive judgment continued to fight for their liberation through their faith in Jesus and through their defiant ideas against the perversity and absurdity of the gender distinction.

Changing Definitions of Gender and Gender Roles in Jainism and Buddhism

As with caste, traditional gender roles as conceived in the orthodox Brahmanical Vedic worldview were challenged by the *śramana* or “striver” movement, of which both the Jain and Buddhist traditions were a part. Although there is some evidence of relative independence for women in ancient Hindu texts such as the *Bṛihadaranyaka Upanishad* and the *Mahabharata*, both of which include strong, assertive female characters, the eventual trajectory of the Brahmanical tradition was in the direction of a subordinate role for women of all castes to their fathers, husbands, and sons (each of these male characters being dominant at varying stages of a woman’s life).

The more relatively liberal and flexible attitudes toward both caste and gender evident in the Jain and Buddhist traditions can be explained in part on the basis of the process of urbanization. It was in urban centers that Jainism and Buddhism had their greatest appeal, and it was in such centers, increasingly common in the middle to late first millennium BCE, that one typically found less rigidly defined caste and gender roles. In fact, such a pattern remains in place in India to the present and is arguably universal. In rural areas, traditional social roles tend to be more rigidly fixed. In urban areas, there is greater social mobility. Besides the textual evidence just mentioned, there is also a good deal of archaeological evidence for a more prominent role for Indian women in urban areas in ancient times, such as inscriptions in which wealthy women have donated funds to the Jain or Buddhist communities for the establishment of mo-

nastic centers or for the feeding on a mass scale of Jain and Buddhist monks.

The first and most obvious place in which Jainism and Buddhism give greater prominence to women is in their monastic traditions. Both Jainism and Buddhism make allowance for women as well as men to take monastic vows. There are Jain and Buddhist nuns, *sadhvis* and *bhikshunis*, respectively, as well as Jain and Buddhist monks, *munis* and *bhikshus*, as they are commonly known in their respective traditions.

The presence of nuns as well as monks in both traditions suggests a belief that women as well as men are capable of attaining the ultimate spiritual goal: liberation from rebirth, known as *moksha* or *nirvana* in both traditions. Indeed, Jain and Buddhist texts are quite explicit in this regard. In the Brahmanical tradition, on the other hand, by the time of the rise of Jainism and Buddhism, it had become customary to believe that one had to be born a male Brahmin in order to be eligible to engage in the monastic practices necessary for the attainment of liberation.

The relative prominence of women in Jainism and Buddhism, however, should not be taken to suggest that these movements were feminist in any sense that would be likely to be recognized in the modern era. In both traditions, women are still subordinate to men. A Buddhist nun, even if she is in her nineties and has been a nun for most of her life, is still junior to a Buddhist monk, even a small boy who has been ordained only a few hours earlier. Indeed, the Jain tradition is divided with regard to the ability of women to engage in monastic practice and attain liberation. The Digambara tradition asserts that a woman is not eligible to engage in the needed practices (which, for Digambara monks, include the practice of mandatory nudity). The Shvetambara Jains, on the other hand, see women as being as capable as men of attaining liberation.

Despite the relative prominence of women in Jainism and Buddhism as compared with the Brahmanical traditions, rebirth as a woman is still seen in both traditions as an unfortunate rebirth and as an impediment to the process of achieving enlightenment. All three traditions—Jain, Buddhist, and Brahmanical—have undergone change

Nuns at the entrance to a temple on Mandalay Hill, Myanmar (formerly Burma). (Marcus Brown)

in subsequent centuries, and versions of feminism now exist in all three. But in ancient times, this was not yet the case.

Gender Roles in China

The Chinese classics, which represent a wide spectrum of views and perspectives, say different things about the role of women within society. Like parts of the Old Testament, some classics, such as the *Book of Odes* (*Shijing*), eighth century BCE, celebrate expressions of female sensuality and erotic love. By contrast, other classical texts, which date much later than the *Book of Odes*, stress the importance of disciplining female desires and erotic power. Liu Xiang's (ca. 79–8 BCE) *Account of Exemplary Women* (*Lienüzhuan*), for instance, glorifies a beautiful widow who was pursued by a king. Refusing to remarry because she saw it as an act of unfaithfulness to her deceased husband, she cut off her nose so as to discourage future suitors. Some other texts, such as the *Spring and*

➤ MOTHERS AND SONS IN HAN CHINA

The great eulogist and official Cai Yong (132–192 CE) wrote an inscription for Ma Lun (d. 183), on the request of her two sons.

“She did not enjoy old age
With long years.
She is gone and will not return,
She has sunken deep into the great darkness.
Alas, sorrowful, indeed!
Tables and mats are set but unused.
The curtains and canopies have been put out in
vain.
Her things are still there.
We do not see her person.
Her ghost drifts about.
How could we pacify her spirit?”

Although scholars tend to see Chinese society as patriarchal, early Chinese elite men, such as Cai Yong, recognized the central importance of the mother-son tie. In the passage above, Cai Yong depicts that the loss of a mother could alter the survivors’ perception of their home environment. Quite strikingly, accounts of sons mourning their mothers far outnumber those by fathers in the Han period.

rose to become virtual heads of state. During the Western Han (206 BCE–25 CE) period, Lü Zhi, wife of the first Han emperor, ruled the empire from 187 to 179 BCE. Assessments of Lü Zhi are mixed. Ancient historians, such as Sima Qian (ca. 145–90 BCE) made much of Lü Zhi’s personal ambitions for her own natal family, which almost led to the end of the Han dynasty. They also stressed her ruthlessness and capacity for violence. Yet by most accounts Lü Zhi was an able ruler and stateswoman. She helped her husband, the first emperor, establish Han rule over the empire during the civil war. More strikingly, her rule coincided with a period of great prosperity and peace for commoners, and she appears to have been a benevolent ruler. The second female virtual head of state was Deng Sui (81–121 CE), who had been the consort of Emperor He (r. 89–105 CE) of the Eastern Han (25–220 CE). Widowed at the age of 25, Deng Sui became the dowager empress, and she ruled the Han empire as the *de facto* ruler from 106 to 121 CE. Modern commentators generally agree that she was an able ruler.

Aside from the consorts of emperors, noble women acquired fame and influence in Han China through their scholarship. Although it is not clear to what extent noble women were literate, a number of them distinguished themselves through their writing. The most famous woman author was Ban Zhao (ca. 48–120 CE), the sister of the famous historian Ban Gu (32–92 CE). Ban Zhao was the author of a number of influential memorials, which she forwarded to the court when it was under the control of Deng Sui. Ban Zhao was also a noted historian. After the execution of her brother, Ban Gu, Ban Zhao took responsibility for completing the court-sponsored *History of the Former Han* (*Hanshu*), on the instigation of Emperor He. She is also famous for her *Precepts for Women* (*Nüxun*), which was addressed to her daughters. There, she urged them to be faithful to their husbands and avoid remarriage.

In contrast to noble women, information about low-status women is rather thin. Yet what evidence survives suggests that low-status women had considerable control over property. As a will dating to 5 BCE reveals, they had the power to inherit property and to distribute it as

Autumn Annals of Lü (*Lüshi Chunqiu*, ca. 237 CE) and *Master Han’s Illustration of Didactic Application of the Classic of Songs* (*Hanshi waizhuan*, ca. 150 BCE), present women as stern and sagacious counselors who used their eloquence and wisdom to persuade rulers to adopt effective policies. Still other texts, such as the *Sayings of the State* (*Guoyu*, fourth–third century BCE), depict the licentiousness of women and the chaos that ensues when women are allowed to interfere with state business.

Noble women wielded considerable power at court during the Warring States (453–221 BCE) and Han (206 BCE–220 CE) periods. Less is known about powerful Warring States women, but during the Han dynasty a number of women

they pleased, even if it meant disinheriting sons in favor of daughters.

Han households drew a distinction between principal wives (*fu*) and concubines (*qie*). Wives tended to be from families of close to equal or equal status to the husbands' families. The sons of wives were the true heirs of their fathers. Concubines, which were the luxury of high-status men, tended to come from lower-status families and enjoyed fewer privileges than principal wives. Women from families with means tended to marry early, most likely in their midteens. Marriage was arranged, and generally their husbands, unless they were widowers, were only a few years older. Women in ancient China faced high infant mortality and the dangers of death from childbirth. While classical authorities frowned on divorce and widow remarriage, both appear to have been fairly common in elite circles as well as lower down the social ladder.

Gender Roles as Revealed on Moche Pots

The Moche, most likely the first ancient Andean society to achieve state-level social complexity, organized specialized centers of production for elite sumptuary goods in the form of textiles, metals, and ceramics. The hand-modeled and -molded ceramics that artisans produced, many elaborately painted, provide scholars with an

Stirrup-spouted vessel depicting a copulating couple, Moche culture, Peru, 100–600 CE. (Werner Forman/Art Resource, NY)

iconographic database for interpreting how women were depicted in Moche art and, by extension, the roles they assumed in Moche society. Generally speaking, women infrequently appear in the entire Moche ceramic inventory, but when they do, they are represented most often as mothers or sexual partners on the vessels produced during Phases I–II (ca. 100–400 CE). Beginning in Phase III and continuing throughout Phases IV and V (ca. 400–800 CE), high-status women occupied more prominent roles in scenes of sacrifice, death, and other religious activities painted in the fine-line style.

Painted and sculptural figures are typically identified as female if they manifest one or more of the following qualities: visible genitals; long hair, often braided; a long shirt or dress with a wide waistband; paraphernalia strongly associated with women (e.g., needles, spindles); and a relationship between figures in which it is reasonable to assume that one of the figures is female (e.g., mother and child, couples engaged in sexual intercourse). One of the earliest and most common iconographic representations of women is that of mother. Moche women are portrayed delivering newborns, nursing infants, and nurturing small children. Moche women are also seen engaged in a variety of sexual relations (anal sex, vaginal sex, and fellatio) with human men but

also with supernatural and skeletal beings. Moche artisans painted other feminine roles pertaining to the domestic sphere with less frequency, but they include preparing food; the making of *chicha*, a type of beer brewed from maize; and weaving with backstrap looms. A Moche IV flaring bowl in the British Museum illustrates a specialized weaving workshop according to Cristobal Campana, who cites it as evidence of women's economic activity during the transition to state organization. Archaeologists working in the Virú Valley have also uncovered weaving implements in female burials, providing additional support to the supposition that women produced wealth by weaving either in a domestic or extradomestic context or perhaps both.

The rise of the Moche state in Phases IV and V coincides with the portrayal of women in positions of social, political, and religious importance. Women operated as shamans and healers, provided a supporting role in organized hunts of both deer and sea lion, and participated in mortuary practices as offering bearers and musicians. At the same time they also entered the iconographic record as supernatural beings according to scholars Anne Marie Hocquenghem and Patricia Lyon, who identified four contexts in which anthropomorphic supernatural fe-

males appear: animated objects, moon/boat, the Presentation or Sacrifice Ceremony, and the Burial Theme. Negative evidence culled from the corpus of Moche imagery suggests that women did not participate in many types of activities (e.g., ceremonial coca chewing, gathering land snails, engaging in ritual battle), and only one of the famed portrait jars known to iconographers displays a female portrait.

■ Introduction: Education

For most people who lived from 1000 BCE to 300 CE, formal education played a minimal role in their lives if it played any role at all. Education was primarily informal. People learned what they needed to know first at home with their families and then while working within the community at large. Most knowledge was gained through practice (learning by doing) or through informal oral means, perhaps from elders within the community or certain individuals (like religious practitioners) with specialized knowledge. However, this was not the case in all parts of the world. The following section of the encyclopedia introduces those types of formal education for which there is evidence from 1000 BCE to 300

CE. Education in the Near East and Egypt remained similar to that in previous periods, so those interested in those regions should consult that section of the encyclopedia.

—Kevin M. McGeough

Greek and Roman Education

Education in ancient Greece and Rome developed on different sets of priorities given the current political and social necessities viewed as important by contemporaries. In classical Greece, Greek city-states such as Athens and Sparta sought to implant good citizenship as

well as provide a well-rounded education for mostly their male population. Greek philosophy, rhetoric, and literature were incorporated into the curriculum, as they were seen as pivotal in provoking thought and stirring pride in Greek cultural achievement. In Hellenistic Greece, Greek education reached its zenith as the fields of medicine, law, and philosophy were extended across the successor kingdoms of Alexander's realm. As Rome expanded in the Mediterranean world, its contact with Greek culture had a significant impact on Roman views on education. While Roman education remained primarily aimed toward practicality, Greek philosophy, language, and rhetoric made headway from the Republic to the Empire periods.

Greek education in classical Athens was geared toward molding mostly elite Athenian men into model citizens who were not only capable of defending the city-state from its enemies but were also familiar with the civic responsibilities and duties of the citizen. Furthermore, Athenians were also well rounded in Greek literature, arts, drama, and philosophy, as these were seen as key in the development of the mind and to instill pride in Greek culture. Greek education emphasized such work as Homer's *Iliad* and *Odyssey* to inculcate myriad Greek historical origins. Early in their education, Athenian boys were made to learn proper grammar, as they would later be expected to use the Greek language for rhetoric and philosophy. Rhetoric, or the art of constructing a persuasive argument, was a key component in Greek education, as it was seen as a means to prepare men for professions in law or for their expected political roles in Athenian democracy. Physical education was also deemed important in the Greek curriculum as a means to imbue students with strength, grace, and beauty through exercise and sport. Greek education in Sparta differed from that of Athens in that it emphasized martial skills far more than it emphasized reading and writing. Women were excluded from learning altogether in classical Greece, as they were relegated to the household and were deemed intellectually inferior to men.

In the Hellenistic period of Greek history, as Greek civilization spread throughout vast regions of the Mediterranean world, the emphasis

Greek red-figure vessel shows students at the Athenian school learning to play the lyre (left); and being instructed in speech, from Cerveteri, 480 BCE. (Jupiterimages)

on instilling pride in Greek civilization became manifest in Hellenistic education. The concept of *paideia* (translated loosely as “education”) became prevalent during this period, as education was seen as a means to instill proper virtues as well as pride in Greek civilization across the Hellenistic ecumene. While emphasizing proper grammar, diction, and elocution, *paideia* also instilled a set of common Greek values. It provided elite men with indoctrination into the ideals and expectations of the Hellenistic intellectual and cultural elite similar to what had been expected in the days of the independent city-states but more associated with the current political situation. *Paideia* created a network of individuals who shared a common education, language, and set of values that extended throughout the Hellenistic world. Furthermore, new centers of learning emerged in the expanded Greek world, such as Alexandria, and these centers became symbols of the extension and glory of Greek civilization. Developments in astronomy, medicine, philosophy, and law, among other scholarly disciplines, further augmented the progress of Greek academia during this period. The great philosophers, Socrates, Plato, and Aristotle, became prevalent as works studied by Greeks throughout the Hellenistic world.

As it existed in the orbit of Hellenistic civilization for centuries, Roman society was deeply

THE LYCEUM

The Lyceum, a gymnasium (school) outside the city of Athens, was a sanctuary to the god Apollo. Greek philosopher Aristotle founded his school of philosophy, known as the Peripatetics, there in 335 BCE and was head of the Lyceum until 322 BCE. The Lyceum was somewhat of an informal educational institution where scholars conducted philosophical and scientific projects and debated over the results. The Lyceum served as a center for Greek learning for centuries, most notably in the field of philosophy, until it was sacked by the Roman general Lucius Cornelius Sulla in 86 BCE. It was subsequently rebuilt, but it never again reached its prior prominence as the intellectual center of the Hellenistic world.

—Abraham O. Mendoza

influenced by Greek educational institutions. Early Roman education focused on shaping Roman men as soldiers and citizens, with the greater focus on the latter. Much as in classical Greece, Roman education emphasized Roman origins, particularly using Livy's *Virgil*, which offered a founding myth for Roman civilization, to stress what were deemed Roman virtues as well as to instill republican values. As the Roman republic gradually absorbed the Hellenistic kingdoms of the eastern Mediterranean as an integral part of its domains, it also attained the cultural and educational legacy that came along with it, with its emphasis on rhetoric and law. However, in Roman education, philosophy was generally deemed as pivotal only so far as it provided moral examples for Roman pupils to follow rather than ruminations on metaphysical questions.

Moreover, the Roman education system developed its own particular pattern of progression in terms of educational levels. Roman education often began in the home under the auspices of a hired tutor or educated Greek slave. While some Romans chose to hire private tutors for their children, many others chose to send their children off to school. At beginning levels, a *ludi magistor*, sometimes a slave or a poorly paid instructor, would teach at an elementary school focusing primarily on reading, writing, and arithmetic primarily in Latin but

also Greek. Papyrus, wax tablets, and the abacus were among the educational implements utilized by students for their lessons. At approximately the age of 12, Roman students advanced to the Grammaticus, where they studied Greek and Roman literature and poetry to instill proper grammar, style, composition, and history. In both these types of schools, discipline was harshly imposed on pupils. Many students were also accompanied by a pedagogue, who was a person specifically hired to make sure the student was attentive to his studies and not easily distracted. At the next level, students wishing to enter careers in politics or law studied under the *rhetor*, where they learned the skills of rhetoric, much like those emphasized under Greek learning. Compositions, speeches, and debate were heavily stressed under the rhetor.

Education in Early China

Indicative of education's overwhelming importance in China is that its greatest historical figure, Confucius, was a teacher. His goal of perfecting one's self could only be obtained through the study of classical texts, which furnished past sages' words and actions. From ancient times, the establishment of schools was an essential government duty. By 500 BCE, education was so important that private education overshadowed its public counterpart. During the Han dynasty (206 BCE–220 CE), Confucianism increasingly dominated school curriculums, thereby securing its grip on Chinese society.

We know little about Chinese schools before 500 BCE. It is clear, though, that governments set up schools for nobles, where they were taught the six arts: ritual, archery, charioteering, music, writing, and mathematics. At this point, martial training was still an essential component of education. During the tumultuous Warring States period (481–221 BCE), the acute need for

talented men led to the emergence of private teachers who would accept paying students from any social class. The first of these masters that we know of is Confucius. This period also saw the first state-funded university, which was founded in the mid-fourth century BCE. Jixia Academy in Qi, which through generous stipends, enticed talented scholars from across China. These academicians became known as *bosbi* (gentlemen of broad learning).

During the Qin/Han period, the government once again attempted to place education under its control. The Qin state did this by banning private education and forcing students to study with officials. The Han did so by establishing public schools. The most important of these was the Taixue (Grand School), which Emperor Han Wudi (r. 140–87 BCE) established in the capital in 124 BCE. In preparation for government service, students here would receive teachings from *bosbi*. Significantly, only the Five Classics (*wujing*) were to be taught at the Grand School. These texts' primary interpreters were Confucian scholars who dominated classical learning. Wudi further mandated that local officials establish a school in each commandery (the empire was divided into 130 commanderies). Creating these institutions was the means by which officials executed their Confucian duty of *jiaohua* (transforming behavior through education). Nevertheless, by 100 CE government schools were in decline.

During the Eastern Han (25–220 CE), private schools educated most people who could afford schooling. Many scholars informally established a school in their hometown. Their disciples could number in the hundreds and even thousands. Younger students were often taught by older students rather than by the master himself. Many students would *youxue* (travel to study) with famous teachers. Private instructors taught a broader array of books than just the Five Classics.

Upon reaching the ages of seven to nine years old, boys would begin to be schooled. Adolescents between ages 15 and 18 could enter the Grand School. By the first century BCE, aristocratic girls also received classical training. Many pupils started their education by reading primers, such as the *Jijiu pian* (*Chapter on Arriving Quickly*). It was organized into seven-character

Qin dynasty emperor Hsien Ti (reigned about 189–220 CE) with scholars translating classical texts, from a history of Chinese emperors, seventeenth century. (Bibliothèque Nationale, Paris/The Bridgeman Art Library)

➤ THE STUDENT LIFE, 100 BCE

The following remarks are from the first century BCE Confucian text, the *Guanzi*. The “Dizi zhi” (Duties of Disciples) chapter furnishes the best early description of student life.

“The master’s teachings are the standards that disciples should follow. A student should be mild, respectful and self-effacing. Upon viewing good, he imitates it; upon hearing of righteousness, he submits to it. . . . He rises early and retires late. His robes and belt must be properly worn. During the day, he increases his knowledge; at night, he reviews it.”

—Keith N. Knapp

sentences and rarely repeated words; teaching literacy was its primary object. Students would then read the *Classic of Filial Piety* and Confucius's *Analects*. Basic mathematics would also be taught. Having acquired a basic literacy, they would then study the Five Classics. It is important to note that students were primarily educated through reading classical texts that bore a strong Confucian imprint.

First Developments in Writing in Mesoamerica

The earliest Mesoamerican writing appeared more than 2,500 years ago prior to the rise of ancient states or the existence of urban centers. Four different pre-Hispanic Mesoamerican writing systems are known: the Maya, Zapotec, Mixtec, and Aztec. Each appears to include a mixture of pictographic, ideographic, and phonetic elements. The Mixtec and Aztec are known from texts written on prepared bark paper or deer skin; the Zapotec system is preserved on inscriptions carved in stone. The Mayan writing system has been preserved in late pre-Hispanic folding books (codices) as well as in a body of texts and painting on stone and pottery.

The most distinguishable feature of all Mesoamerican scripts is the highly intricate and pictorial form of signs. They are often called hieroglyphic in analogy to Egyptian hieroglyphs since their symbols are highly pictorial. For this

reason, a sign from Mesoamerican scripts is often called a glyph, as a short form of the term "hieroglyph." Visually, Mesoamerican scripts resemble each other and share many similar glyphs.

The principal subject matter of these texts was historical and sociopolitical "propaganda" regarding rulers' histories, state histories, conquests, and genealogies. These included dates, place names, and captives conquered and then sacrificed, but writing was also linked to counting of time and astronomy.

Bar-and-dot numerals are among the first recognizable written signs in Mesoamerica and probably were part of a representational system ancestral to all Mesoamerican scripts. By circa 1100 BC in the area of the Gulf Coast of Mexico appeared the first signs of what is known as the Epi-Olmec script. La Mojarra Stele is one of the first readable scripts in Mesoamerica. Discovered in southeastern Veracruz, Mexico, in 1986, this stele is a basalt slab measuring 7.6 by 4.6 feet (2.34 by 1.42 meters) with two long-count dates: May 1, 143 CE, and June 23, 156 CE. The text describes ritual bloodletting, warfare, and political intrigue during the reign of the Harvester Mountain Lord, the figure depicted on the stele. However, Stele 1 of La Mojarra is not the only example of this writing system. Most of the monuments that bear glyphs in the same (or similar) writing system are also found near the Isthmus of Tehuantepec. The famous Tuxtla Statuette bears a long-count date of 162 CE as well as noncalendric glyphs. Other famous inscriptions include Stele C of Tres Zapotes, with a long-count date of 32 BCE. In the site of Cerro de las Mesas, Veracruz, highly eroded monuments also bear long-count dates but from the Early Classic period of around 450 CE, as does a large stone version of the Tuxtla Statuette, which is devoid of any text.

■ Introduction: Food and Cuisine

Food is not just for eating. It can act as a means of bringing people together or demonstrating differences between groups. Meals are profoundly social times, and taste in cuisine is highly variable. Given how distinctive food is from one culture to another, it should not be surprising that the experiences of cuisine vary dramatically throughout world history. While many ancient cuisines are lost to us, it is often possible for historians and archaeologists to reconstruct ancient eating habits and their cultural significance.

The following set of entries seeks to explore the different social roles of food that can be identified throughout the world from 1000 BCE to 300 CE. The religious roles of food are examined, from the use of food in ritual banquets to the establishment of dietary restrictions (such as kosher laws) based on spiritual values. Food as a status symbol and especially as a means of displaying wealth is also an important topic discussed here. And of course, the importance of food in building social relationships and, as in the case of alcohol, facilitating good relations between people is discussed as well.

—Kevin M. McGeough

Development of Dietary Restrictions in the Ancient Near East

Dietary restrictions in the ancient Near East emerged at different times and under different circumstances. In most cases, the reasons why certain plants or, more commonly, animals became prohibited for human consumption are not clear; however, issues of hygiene and health and of inappropriate behavior on the part of the animal and its reflection, if eaten, on the larger society are among the stronger candidates. Other factors were also at work. Dietary restrictions may be confined to certain time periods or events (say, a holy month or the dedication of a temple) and may include prohibitions against all food and drink (in the case of fasting). While they universally served to set off one group from

another and generally served as a religious symbol of purity, devotion, and/or status, dietary restrictions varied from region to region and changed over time. Given these complications, they should always be considered on a case-by-case basis, with careful attention to not only their historical contexts but also the nature and limitations of the evidence, which is often contradictory.

Egyptian dietary restrictions in the first millennium BCE are largely influenced by Herodotus, the “father of history.” According to him, the principal taboo animal was the pig, which was not even touched by the Egyptians because of its association with Seth, their chief deity, and his representation, the so-called Typhonic animal. The scarcity of the pig in Egyptian art lends support to this theory; however, the numerous attestations of pigs in offerings to other deities, not to mention textual and archaeological data showing that they were both reared and eaten in Egyptian society, speak against Herodotus’s claim, at least for earlier periods. Perhaps the taboo arose just before Herodotus’s day (i.e., the fifth century BCE) or was limited to certain individuals or events, as considered above. In addition, Herodotus mentions a taboo against fish, as does Diodorus of Sicily, the two differing on whether it applied to priests alone or to the entire population, respectively. Both their claims may be supported by Piya’s victory stele, which mentions such a taboo in the eighth century BCE. Here too, however, archaeological and artistic evidence suggests that the prohibition was not strictly followed.

Dietary restrictions from ancient Israel and Judah are among the best known and most comprehensive from the ancient Near East. The early roots of *kashrut*, the general set of laws dealing with religious correctness that is particularly associated with diet, are found in the Hebrew Bible (or the Christian Old Testament). There, dietary restrictions are found against the consumption of blood (Genesis 9:3–6), the “sinew of the thigh” (Genesis 32:33), the boiling of a kid “in the milk of its mother” (Exodus 23:19 and 34:26 and Deuteronomy 14:21), and the eating

► BIBLICAL DIETARY REGULATIONS—RABBITS EATING CUD

The dietary restrictions found in Leviticus 11 and Deuteronomy 14 often give further details on why a particular animal is permitted or prohibited. In elaborating on the condition that land animals must have divided hoofs and cleft feet and chew the cud, it offers the following: “But among those that chew the cud or have divided hoofs, you shall not eat the following: . . . [t]he hare, for even though it chews the cud, it does not have divided hoofs” (Leviticus 11:4–6; New Revised Standard Version). Of course, the rabbit does *not* chew the cud, but it is very reasonable—even charming—to see why this statement is here: As anyone who has seen a rabbit will attest, the constant motion of their noses makes it look like they are chewing! That is assuredly what the ancient author had in mind. Nevertheless, some commentators consider the author technically correct here since the rabbit practices refection, a process whereby it eats its own waste, thus “bringing up” the cud (i.e., chewed food) again. Had the author written the passage with this in mind, they would most assuredly have given a very different reason for prohibiting the rabbit.

—Benjamin Studevent-Hickman

of the Passover sacrifice (Exodus 12:8–14), but these are difficult to date. Aside from the prohibition against blood, which formed part of the covenant with all humanity after the flood, by far the most extensive set of prohibitions is found in the list of permitted and prohibited animals in Leviticus 11 and Deuteronomy 14, many of which bear additional explanations. According to these laws, permitted animals include land animals that have divided hoofs and cleft feet and chew the cud, with exceptions; water animals with fins and scales; birds, with certain exceptions; and winged insects with jointed legs that are used specifically for jumping (i.e., the locust, cricket, and grasshopper). These laws no doubt date to the first millennium and form part of a larger historical development whereby the ancient followers of what would become biblical texts further defined themselves and their devotion to Yahweh, their God. Of particular note

among these laws is the fact that the pig is not considered particularly unclean: it is simply one among a number of land animals that do not fit the criteria. Needless to say, the notion of dietary restrictions went to the core of Israelite thinking. According to the biblical tradition, the fact that Eve and Adam violated a dietary restriction by eating from the Tree of Knowledge of Good and Evil—the only food in the Garden of Eden narrative that was off limits to them—is the very reason that humans must ultimately work for their food.

The Wine-Based Symposium in Greek Culture

The wine-based symposium served an integral social and cultural function in ancient Greece. While often translated as a “dinner party” or a “banquet,” the symposium was literally a “drinking-together” and involved only the consumption of wine, although it was preceded by a communal meal. It reflected the social segregation characteristic of ancient Greek society, as participation was limited to aristocratic males.

During the Archaic period the symposium served as an important nexus for the transmission of aristocratic values through both the performance of poetry (the poetry of Theognis is particularly illustrative of this aspect) and male bonding. The homoerotic element of the symposium was intertwined with its initiatory function during this period, for young aristocrats served

Reclining man and aulos player depicted on an Attic red-figure cup, about 500–464 BCE. (Bildarchiv Preussischer Kulturbesitz/Art Resource, NY)

as cupbearers and sometimes lovers to their older mentors. By the Classical period in Athens and many other cities, aristocracies had lost their dominant role in politics and society to democracies, and the symposium became marginalized, offering a private (elite) alternative to the public fora of the democracy, sometimes with a subversive political focus. Accordingly, the earlier initiatory function was no longer relevant, and the participants were now all adult male citizens.

The symposium was a highly ritualized occasion. It took place in the *andron*, the domestic chamber limited to males. Participants, usually numbering between 7 and 15, reclined on couches (a custom imported from the East) with 2 people per couch. After the removal of the dinner, which did not include wine, the guests cleansed their hands, put on garlands, and anointed themselves with perfumed oils. Then a libation (a type of offering) was made with undiluted wine (this was the only time when the Greeks did not mix their wine with water) accompanied by a hymn to the gods. One participant, the symposiarch, was selected to lead the proceedings, and he determined the ratio of water to wine (usually between three and four parts of wine to one part water), the size of cups to be used, and the number of drafts. The entertainment then commenced and consisted of conversation (facilitated by the square ar-

▶ PLATO'S SYMPOSIUM

Plato provides a literary representation in the *Symposium*. This extract, in which the doctor Eryximachus assumes the role of *symposiarch*, illustrates the unusually intellectual and erotic atmosphere of the symposium in Plato's dialogue:

"Well then," said Eryximachus, "now that it's agreed that each of us should drink as much as he wants, without any kind of compulsion, my next proposal is that we should send away the flute-girl who's just come in, and let her play for herself, or for the women in their part of the house, if she prefers, and that we should spend the evening in conversation. Also, if you're willing, I'd like to propose a topic for discussion. . . . I propose that each of us should make the finest speech he can in praise of Love, and then pass the topic to the one on his right."

—Frances Pownall

Plato, *Symposium*, trans. Christopher Gill (New York: Penguin Books, 1999), 176e–177d.

range of couches in the andron), the singing of poetry (to the accompaniment of flute girls), the playing of drinking games, and the performance (sometimes overtly erotic) of dancing girls. The symposium concluded when the allotted number of drafts had been consumed, sometimes with a ritual (often drunken) procession in the street.

Roman Banquet and the Use of Food and Setting for Status Displays

Romans ate three meals during the day: breakfast (*ientaculum*), lunch (*prandium*), and dinner (*cena*). Breakfast and lunch were slight affairs often consisting of little more than a cold snack. The poet Martial ate bread and cheese for lunch, and Seneca ate a piece of bread for lunch.

The main meal of the day was the dinner that began at the eighth hour and continued until dusk. Dinner would take place in a *triclinium* (named as such after the three couches upon which the guests would recline while eating). The couches would be placed around three sides of a square table and would each house three diners. Placement was hierarchical, with the most distinguished guests reclining on the couch facing the empty side of the table—the *lectus medius*—upon which the right-hand place was the most senior. The meal itself was an elaborate one consisting of up to seven courses: the hors d'oeuvres, three entrées, two roasts, and the dessert followed by drinks.

The most famous account of a dinner party is that of C. Pompeius Trimalchio that is recounted in Petronius's satirical *Satyricon* written during the reign of the emperor Nero (54–68 CE). Trimalchio dazzles his guests with an array of fabulous foods: iced water from Alexandria, dormice in honey and poppy seed, peahen eggs, a dish made

up of foods representing the different signs of the zodiac, and an imitation goose garnished with fish and birds that is in fact made of pork. In Juvenal's account of a dinner hosted by Virro, the guest of honor enjoys crayfish, goose livers, African truffles, and freshly baked bread. Dinners were enlivened with suitable entertainment: Trimalchio has acrobats, trumpeters, a flautist, and comic actors. According to Suetonius, the emperor Augustus entertained his guests with performers, pantomimes, circus performers, and storytellers. The emperor Hadrian provided tragedies, comedies, farces, musicians, readers, and poets.

Although the Roman Senate sought to restrict the excesses of dinner parties, the Lex Fannia of 161 BCE sought to limit the number of guests and the amount that could be spent on food. These events remained important opportunities for high-class Romans to display their wealth and patronage. According to Cicero, it was important for a man of status to enjoy housing appropriate to his status. The efforts of the Senate were not successful, and the owner of the House of the Moralist in Pompeii decorated his triclinium with admonishing graffiti: "Keep your wanton expression and flirty eyes off another's wife. Show some restraint!"

Social and Religious Uses of Food in Vedic India

In ancient India, religious merit, social status, political power, and interpersonal relations all depended on food and food transactions. From

Triclinium of the House of the Ephebe, Pompeii. (Benedict Lowe)

at least the time of the Vedas (ca. 1300 BCE), food was a central requirement for religious rituals. During the Vedic fire sacrifice, priests placed a variety of food substances into the ritual fire. The fire sacrifice was said to be a powerful way of acquiring benefits in both this world and the next. Agni, the god of fire, was thought to carry the oblations to the rest of the deities. Offerings of milk, clarified butter, grains, and meat were common, as was a hallucinogenic drink made from the plant soma. The priests performing the sacrifices and the sponsors paying them would receive a share of many of these foods. For example, a sacrificed animal would be butchered, with part placed in the sacrificial fires and the remainder given to the priests and sponsor. The rise of Buddhism and Jainism in the sixth century BCE challenged this system. Both religions rejected the Vedic claim that sacrifices would ensure the sacrificer a heavenly reward. Instead, they stressed the horrific karmic consequences of such sacrifices. Jainism in particular required that its adherents maintain a vegetarian diet, and likely due to Jainism's influence on general Indian culture, vegetarianism came to be adopted by many Hindus.

When Vedic sacrifices were replaced by temple-based worship in the first millennium CE, people continued to use food in worship. During the typical *pūja* (worship ritual), a statue of the deity is given fruit or cooked food to eat and is bathed in milk, melted butter, honey, and similar substances. The foods and liquids from the ritual are called *prasād* and are consumed afterward by worshippers. This was thought to convey the deity's blessing to the devotee. Many deities are thought to have a fondness for particular foods, such as the god Krishna's fondness for butter. That Krishna spent his youth as a cowherd likely contributed to the Hindu avoidance of beef.

Food and food transactions signaled social status and shaped interpersonal relations. Different social groups followed different diets. At the beginning of the Common Era, legal codes such as *The Laws of Manu* provided guidelines on what foods were permitted. They also forbade members of different castes from dining together. The higher in status a caste, the more restrictions existed on what foods its members

➤ LAWS OF MANU ON FOOD

"You may eat meat that has been consecrated by the sprinkling of water, or when priests want to have it, or when you are properly engaged in a ritual, or when your breath of life is in danger. The Lord of Creatures fashioned all this (universe) to feed the breath of life, and everything moving and stationary is the food of the breath of life."

—Katherine Ulrich

Wendy Doniger with Brian K. Smith, trans., *The Laws of Manu* (New York: Penguin, 1991).

might eat. Although it is difficult to say how widely the rules were followed, some at least would have adopted them. Many high-caste groups were vegetarian, particularly members of the priestly caste. The third-century BCE emperor Aśoka, influenced by Buddhism and Jainism, claimed in one of his edicts that the many animals once killed in the royal kitchens had been reduced to a single deer and two peacocks. Kings were expected to provide alms for religious mendicants, and many left records indicating that they did so.

Food and Its Uses in Chinese Religion and Social Life

Food was of overriding significance in early China. It was the glue of Chinese political, religious, and social life. It bound men to each

➤ WARNINGS ABOUT FOOD IN THE *DAO DE JING*

The *Dao De Jing* warns readers about the dangers of concerning oneself with material luxuries such as food in place of religious and spiritual issues. Chapter 35 argues that whereas food and music may appear to be more interesting than philosophical inquiries, the value of following Daoist practices is priceless. It reads: “Passersby may stop for music and good food, But a description of the Dao Seems without substance or flavor. It cannot be seen, it cannot be heard, And yet it cannot be exhausted.” Chapter 53 warns about hoarding wealth, including food. It reads: “Some wear gorgeous clothes, Carry sharp swords, And indulge themselves with food and drink; They have more possessions than they can use. They are robber barons. This is certainly not the way of Dao.” Both are situations where the love of food was thought to lead practitioners away from the Dao.

other, the living to the dead, and even people to the gods. Food was used to demarcate social status; in this society you truly were what you ate. How one ate was also a serious matter that disclosed one’s moral character and upbringing. What one consumed also could earn one religious merit or even immortality.

During China’s earliest historical dynasties, the Shang and the Western Zhou (1045 BCE to 771 CE), food was of central political importance. Early rulers believed that their state’s welfare depended upon their powerful ancestors’ goodwill. Nothing was more important than keeping them happy. Rulers did so by nourishing them with offerings of food and drink. Doing so was of such importance that the dead were interred with ritual bronzes, enabling them to continue to make sacrificial offerings in the afterlife. By the late Warring States period, the sacrifice of food was so momentous that the possession of nine mythical bronze tripods, a type of offering vessel, became a symbol of imperial

legitimacy. Food connected humans to deities and ghosts who likewise needed offerings of food and drink. However, the food offered to them was raw or uncooked, indicating their separation from humans.

Food was an essential indicator of social status and hierarchy. In pre-Qin China, meat left over from the sacrifice (since the spirits will only ingest the meat’s essence) would then be distributed to friends and allies. The quantity of blessed meat one received indicated one’s importance; as a result, aristocrats were called meat-eaters. In early imperial times, food continued to be used to indicate one’s status. People regarded meat, wine, and rice as upper-class foods, while vegetables, millet, beans, and water were lower-class foods. For instance, upon inviting the well-known literatus Guo Tai to his home, the filial son Mao Rong slaughtered a chicken, which Guo thought was meant for him. Mao instead fed it to his mother, while he and Guo shared a meal of vegetables. By treating his mother with such esteem, he earned Guo’s admiration. Upper-class people who wanted to display frugality and selflessness would eat lower-class fare.

Feasting was the central feature of all social events. For the vast majority of people, these must have been among the brightest moments of life: sharing good food, drink, and conversation with people who mattered to you. Since music was performed and acrobats and jesters supplied entertainment, banquets among the upper class must have been particularly enjoyable. This is probably why depictions of feasts are so common in Han dynasty mortuary art. Nevertheless, banquets fulfilled important social functions as well. They reinvigorated feelings of solidarity and group identity while underscoring the group’s hierarchy; those who sat closest to the host were obviously the most important. Feasts were also a means to motivate a person to act on your behalf; lavishly feeding someone was a means of creating a debt of obligation in the recipient. Since elaborate regulations governed behavior at these communal meals, they also furnished an opportunity to gauge a man’s character and knowledge of etiquette.

Eating in itself was an important religious act. For Daoists, one could achieve immortality by avoiding consumption of ordinary food; in-

stead, one ingested spiritually enriching nutrients, such as *qi* (energy, ether), medicinal plants, and mineral-based elixirs. Daoists and Buddhists thought that at sacrificial banquets lay devotees should avoid impure food, such as meat or the five strong-smelling vegetables (such as garlic and onions). Concerns with the ethical implications of killing animals for food later led Chinese lay Buddhists to embrace vegetarianism.

Use of Wine, Beer, and Mead in Celtic Society

Consumption of alcoholic beverages was an important element in Celtic cultures in late prehistory. Containers for alcoholic drinks have been found in many of the elite burials across prehistoric Europe and testify to the importance of alcohol in burial rites. The most prominent examples are the Krater (mixing bowl) from the late Hallstatt burial in Vix, France, a Greek import, with a volume of approximately 37,206 ounces (1,100 liters), and the bronze cauldron from the late Hallstatt burial from Hochdorf, Germany, with a volume of approximately 16,912 ounces (500 liters). The contents of the latter have been analyzed and produced evi-

dence that it contained honey-mead or sweetened wine. The Hochdorf burial also contained nine drinking horns, the largest of which was 4 feet (1.2 meters) long and had a volume of approximately 186 ounces (5.5 liters). Similarly, the two flagons from the early La Tène burials 1 and 2 from Glauberg, Germany, most likely contained honey-mead, with the honey used at least partially imported from areas well over 62 miles (100 kilometers) from the actual burial site.

Further evidence is provided by the goods imported into Iron Age central and western Europe from the Mediterranean zone, most of which clearly are associated with the consumption of alcoholic beverages. This starts out as early as the late Hallstatt period, with Greek wine amphorae and wine drinking cups being the primary import goods. It continues throughout much of the early La Tène period, where northern Italian beaked flagons as well as local imitations frequently appear in elite burials as the main item of southern import. The peak of imported wine, however, is reached during the late second and first centuries BCE during which

► A GREEK HISTORIAN DISCUSSING THE GAULS' DRINKING HABITS

They [the Gauls] are so exceedingly given to wine, that they guzzle it down as soon as it is imported by the merchant, and are so eager and inordinate, that making themselves drunk, they either fall dead asleep, or become stark mad.

imported wine amphorae are found in Gaul, southern Germany, and southern Britain, in such high numbers that estimates speak of more than 353,000 cubic feet (10,000 cubic meters) being imported annually.

While consumption of alcoholic beverages seems to have generally been widespread in late prehistoric Celtic Europe, high-status drinks, particularly imported wine and possibly also locally produced honey-mead, seem to have played major roles in the region's political economy and the legitimization of power. There is historical evidence of Celtic chieftains providing lavish feasts for their respective communities in which the consumption of imported wine seems to have played a major role, indicating that the ability to procure larger amounts of such drink was important in creating and maintaining power relationships.

■ Introduction: Leisure

The origins of many of the types of leisurely pursuits that we engage in today can be found in the world cultures that existed from 1000 BCE to 300 CE. This was the time when reading (as opposed to listening to stories read aloud by another) became an important activity in Europe, Asia, and parts of North Africa. Music and dance continued from previous periods, but the traditions of Europe, India, and China today are in many ways still influenced by the traditions of this earlier time. Likewise, the Greek theater provided a model for dramatic performances that has been so powerful that Greek plays are still performed today. Even the basic layout of a modern theater is that established by the Greeks and further modified by the Romans. Sport, as we think of it today, is rooted in this Classical period, from the activities that one might pursue in a gymnasium (an

institution first found in Greece) to watching a football match (with its origins in Mesoamerica) in a large public arena (with its origins in the amphitheaters of the Romans).

Development of the Concept of Sport in the Greek World

Athletics and religion were inextricably linked for the ancient Greeks from the first recorded references to athletic contests in Homer. In the *Iliad*, Achilles holds funeral games in honor of his close friend, Patroclus, that include a chariot race, a footrace, wrestling, and boxing. These became the main athletic contests in later periods of Greek history. The belief that the gods

were interested in and pleased by the results of excellence (*arete*) in individual competition is omnipresent throughout the Homeric epics and resulted in the incorporation of athletic contests into religious festivals in honor of specific deities.

By the beginning of the Archaic period, regular Panhellenic (that is, open to all Greeks) festivals arose in which the wealthy elite competed with one another outside their local community. The athletes competed in the contests, whereas the spectators competed in the wealth and splendor of the offerings they made to the gods (eventually large treasure houses were built at the sites of the festivals to hold these costly gifts). These Panhellenic festivals contributed to the cultural unity of the Greeks, who remained politically divided especially in opposition to their foreign neighbors, whom the Greeks called barbarians (non-Greek speakers).

The earliest Panhellenic festival was the Olympic Games in honor of Zeus in the remote site of Olympia in the northwestern Peloponnese. According to a list of Olympic victors compiled in the fifth century BCE, the first games were held in 776 BCE, although Greek tradition holds that the games were founded either by Heracles or by the hero Pelops to commemorate his victory in the chariot race over a local king. The only event in the first Olympics was a sprint of about 656 feet (200 meters), but over time more footraces along with other events were added. The Olympic Games were held every four years in the late summer. By the fifth century BCE the Greeks had developed a standardized dating system based on the four-year periods in between the Olympic Games.

During the late seventh and sixth centuries Panhellenic festivals were instituted at other sanctuaries. The Pythian Games at Delphi honored Apollo, the Isthmian Games honored Poseidon and took place near Corinth, and the Nemean Games were held in Argolid in honor of Zeus. These festivals formed a circuit around central Greece, more specifically the commercial hub of Corinth, and were held at either two-year or four-year intervals. They were staggered in order to allow a competitor to compete in either one or two major venues each year. The Olympics remained the most prestigious venue

Roman copy of the fifth-century-BCE bronze original of Myron's Discobolus. (Corel)

and was normally accompanied by a sacred truce banning interstate conflict. This permitted safe travel to Olympia from far-flung regions of the Greek world. There were also local festivals held in individual city-states.

The athletic competitions included only individual events and thus remained true to the warrior ethos of the Homeric epics. Most athletic competitions centered around six main categories of events. The footraces included the *stadion*, a race slightly under 656 feet (200 meters), or the length of the stadium; another longer race of approximately 1,312 feet (400 meters); and a distance race of varying lengths. By the end of the sixth century the Greeks had added a race run in full hoplite armor, which illustrated the close connection between athletic competitions and military training. There was no marathon, although the modern marathon springs from the apocryphal tradition that an Athenian runner

ran from Marathon to Athens to announce the Greek victory over the Persian invaders in 490 BCE and then immediately dropped dead from exhaustion.

Wrestling and boxing were two other standard Olympic events. Boxers did not wear gloves but instead wrapped their arms and forearms in heavy leather thongs. There was also the *pankration*, an aggressive and dangerous combination of boxing and wrestling in which the only restrictions were biting and eye-gouging. One unscrupulous athlete was famous for his penchant for bending back the fingers of his opponents. The pentathlon was a combination of five different events: the stadion, javelin, discus, long jump, and wrestling. The equestrian events included both horse races and two- and four-horse chariot races. These differed from the other events in that the owner of the horses rather than their rider or driver was the winner.

Prizes at the major Panhellenic festivals held only symbolic value. Winners received wreaths of leaves: olive at the Olympic Games, laurel at the Pythian, pine at the Isthmian, and wild celery at the Nemean. At other festivals, however, the prizes sometimes included generous monetary compensation. Upon their return home the winners did receive fame and often fortune, such as statues, free board for life, and other civic honors. Poets such as Pindar composed victory odes for the winners at the Panhellenic festivals.

Competition in the Panhellenic festivals was open to any free-born Greek-speaking male. Separate competitions were held for men and for boys. Women were not allowed to compete (although they could enter chariots in the competitions), nor were married women permitted as spectators. Unmarried women could attend, presumably to allow marriage arrangements to be made. There were separate women's games, the most famous of which were footraces held at Olympia in honor of Zeus's wife, Hera.

Role of Leisure in the Hellenistic and Roman Worlds

Leisure played a distinctive role in the lives of both the ancient Greeks and Romans that fit within their worldview on the dual roles of work and play. The ancient Greeks perceived leisure as a time devoted to the pursuits of pleasure for the sake of enjoying the greatness of the Greek city-states. This attitude carried on from the ancient period to the Hellenistic period of Greek history. In this sense, leisure was perceived as an outlet to pursue the joys of life in a manner that sated body, mind, and soul. On the other hand, Romans perceived pleasure with extreme distaste as something that corrupted morals and created opportunity for corruption and vice. However, elite Romans disdained work as something that fouled human relations and was to be avoided by people of their life station. Both Greeks and Romans developed entertainments and recreations to fit their perceptions of how to enjoy their time not at work. Leisure took on a distinct and unique shape in ancient Western civilization in both these cultures.

Hellenistic Greek philosophy discussed the duties of the citizen of the Greek states to his polis and how this fit within his own betterment as an individual. Stoicism, the philosophy of thriving in one's duty, was perhaps the only Greek philosophy that did not advocate such a stance. Epicurean philosophy encouraged partaking in pleasures in one's leisure time as a way to live life to its very fullest. While work was important to the day-to-day life and productivity of the average Greek, leisure time was seen as an opportunity for individuals to enjoy the benefits of Greek culture. Taking pleasure in life was seen as an outlet for which to partake in the joys of life, which contributed to the mental and social edification of the individual. Leisure time allowed citizens of

the polis time to find substance in recreational activities that not only allowed them to enjoy their time off work but also enjoy the material and intellectual wealth of their city-state.

Greek leisure time was devoted to pursuits that enriched both the body and the mind and were generally accessible to all citizens, with the exclusion of slaves. Greek athletics, in the form of gymnastics, sports, and competitions such as the Olympics, encouraged individual Greeks to display their physical prowess and the natural beauty of the body. Physical strength and endurance illustrated the military might of a particular city-state, such as Sparta and Athens, while also displaying the beauty of the human body. The ancient Greeks viewed physical beauty (*kalos*) as representative of the good (*agathos*). Festivals and celebrations, particularly religious festivals, were also opportunities for Greeks to come together and enjoy the benefits of the city-state. The rituals and religious processions, in addition to feasts, allowed average Greeks to partake of events together while appeasing their gods. Much like athletic events, religious festivals and feasts allowed people to come together and enjoy the bounties of life in the form of entertainments, food, and recreation.
